The propagation of this very showy plant may be effected in this wise. At this season of the year, when growth is matured, select cuttings 8 or 10 inches in length; insert each in a small bottle of water, with a pinch of wood-charcoal in each bottle, and place the bottles in a warm house, such as a plant-stove, or any other place, where the heat is not less than 60° or 70°. In a month or six weeks these will be rooted, when they may be potted in as small pots as possible, without injuring the roots, using loam and river sand in equal proportions; but they do not seem particular as to soil, provided it is wholesome, and the pots are well drained. If kept in a warmish place, with moisture in the atmosphere, they soon get established in their second progressive state. In early spring, as the days lengthen and growth commences, give them more moisture and heat, and towards April they may be shifted into a size larger pot. By no means give them too large a shift. A lively heat and an abundance of moisture will be all they need till they show signs of flowering, which they will do about August. The admission of plenty of air, and partially withholding water for a month at this period will be a rest to them; they may then be put into a warm moist heat as before, and their flowers will open in abundance in October, and on to Christmas. Some, of course, will not show signs of flowering the first season; these may continue on in a cool resting temperature during the winter, when in early spring they may be started into growth; and these will mature their shoots and flower in summer and early autumn. It must be borne in mind that the Oleander requires a liberal supply of moisture, both at root and branch, when growing; and, on the other hand, it must not get into a stagnant state, so that caution must be exercised in giving a very liberal drainage in all cases. In a planted-out state the Oleander makes a splendid bush, and throws out great shoots 4 or 5 feet long, which throw splendid trusses of bloom, some of the individual flowers measuring 1 inches in diameter. Of course the Oleander requires no shade, and every ray of sun must be given to the plants at all times. The variegated-leaved form is very pretty, but its flowers are not nearly so fine as those of the green kinds; this does not strike well, and it is better grafted on the green. There seem to be only two or three kinds known in this country to any extent, and it is pleasing to learn that the Messrs. E. G. Henderson and Son have some beautiful single varieties, with large improved flowers, which may prove great acquisitions to the flower-forcing gardener. The white one will be a valuable addition; and, though not new, Messrs. Henderson deserve universal thanks for bringing it before the public.—*Florist*. [The yellow-flowered variety, also, should not be lost sight of.]

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pittosporums.—I have the old-fashioned *P. Tobira*, now a much neglected plant; but I hear there are others equally handsome. Can you name one or two, and say in what soil they succeed best.—*CLARA*. [The common species is *P. Tobira*; but we occasionally meet with *P. japonicum*, which has larger flowers, and handsome glossy foliage. All the species are suitable for indoor culture. They do well in a mixture of peat and loam, and require no care except to be regularly watered and to be kept clean.]

Fourcroyas.—Two or three species of *Fourcroya* are now in bloom in the succulent-house at Kew. In general appearance and habit they closely resemble American Aloes, or Agaves, while their large white flowers remind one of those of the Yuccas, the stamens being inserted in a similar manner, and rarely protruding beyond the tube or floral segments, as is the case in the Agaves. A striking peculiarity exhibited by these plants is the production of little bulbs on the flower-spikes in place of seed-vessels, while the plants do not generally evince a tendency to throw up suckers or off-sets so freely as the Agaves.—*L.*

Gesneras.—Many of these dwindle away with me after flowering, and sometimes die outright. How can I prevent this?—*S. Bickton*. [To keep them in good health, they must be well attended to after flowering, for then the bulbs for the following season have to be matured. In order to effect this, they should be carefully tended, giving them occasional waterings with weak liquid manure; but as the foliage begins to decay, less water will be required, and when the growth is finished, it must be entirely withheld. After this, though requiring to be kept dry, they must not be baked, but should be stored away in their pots in a dry place free from frost until again required. It is a common practice to shake the soil away from them when dry, and to store the bulbs in dry sand; but we believe the best system is to leave them in their pots, and just start them into growth in the old soil before re-potting, for by this treatment the bulbs are not so liable to injury as they otherwise would be.]

Acacia lophantha, Melianthus major, and other Indoor Decorative Plants.—I can fully endorse all that "A. B. N." says (see p. 380) as to the value of *Acacia lophantha* for indoor decorative purposes. Seed of it sown in autumn will, if well grown, produce fine strong plants by the following autumn. Plants from spring-sown seed will, of course, be smaller, but, for certain purposes, better than those raised from autumn-sown seed. They should be plunged in a bed of ashes in the open air during the summer and early autumn months, care being taken that they are not crowded, or they lose their lower leaves, and, with them, half their beauty. Another plant of first-rate excellence for decoration, and as easily grown as the above, is *Melianthus major*. It should be sown in March and started in heat, and from June onwards treated like the *Acacia*. There are few handsomer plants than the *Melianthus*. Its unusual colour and finely-formed leaf and free graceful growth always attract attention, and it is one of those plants which everybody admires. *Capsicum Prince of Wales* and *Yellow Gem* are also very pretty for autumn and winter decoration. They retain their bright yellow berries for a long time, and well repay any little attention which their growth requires.—*E. B.*

ARTIFICIAL ROCK-WORK AT OATLANDS PARK.

ROCK-WORK, as a picturesque feature in garden scenery, is often attempted, but seldom with complete success. I am not alluding to decorations of this kind put unskilfully together, as they generally are in the small gardens of suburban villas, but to such rock-work as it is pretended shall have the appearance of being a natural outcrop of the rock formation of the district. There are two very distinct modes of producing the effect of natural rocks, both of which require the exercise of considerable artistic taste, as well as much practical skill. The one is by excavation, and by that means of exposing the face of rocks previously hidden beneath the surface; and the other by building up, with suitable materials brought from a distance, and in that way forming masses of rock having a natural aspect. Of these the most obvious and least expensive method (should external appearances indicate the presence of rock at no great depth from the surface) is to excavate, and so lay bare the natural rocks. I have seen several gardens of from 5 to 20 or 30 acres in which this system has been practised with more or less success. The favourable lie of the ground, or otherwise, is always an important matter in cases of excavation. One or two rocky valleys thus excavated that have come under my notice, have looked much more like Nature's own production, than that of the pick and spade. I have, too, seen places in which the natural conditions presented admirable facilities for carrying out the creation of such a scene by excavation, but which, from a tasteless spottiness in the management (or, rather, mismanagement), were worse than failures. I say, advisedly, worse than failures; because the place, which was naturally pretty, with soft green slopes, plenty of trees, and a glimpse of sparkling water, had been dug into meaningless ugly holes. I have also seen both noble and ignoble specimens of built up rock-work. Without amply sufficient space it is difficult to produce a natural and broadly artistic effect. I have, however, met with specimens of this kind of garden landscape-work in which, although both space and materials have been limited, the effect has been all that could be desired. I have also seen such work, on a gigantic scale, where the result has been lamentably bad. In the grounds of Mr. Hewitson, at Oatlands Park, a piece of rock-work has been built, in which Nature has been imitated with such complete success as to wholly exclude all traces of art. The undulations of the ground, the turfy slopes of which become exceedingly steep as they approach the lake, presented, it must be confessed, unusually favourable points for an apparent outcrop of rock; and of these the very fullest advantage has been taken, and with consummate taste. The beautiful grounds in which these effects of rock-work have been so artistically simulated, form part of the once royal park of Oatlands, some 30 or 40 acres of which Mr. Hewitson was so fortunate as to secure, at what would now be deemed an almost nominal price. The powers "that were" decided, in their collective wisdom, to sell the fine old park, piecemeal, by auction, to the highest bidders, in order to save the expense of keeping it up; its noble historic trees being valued to the purchasers at common timber price, by carpenters' measurement. Among those trees are some Cedars, which must rank among the grandest and most picturesque in the land; and there are several gigantic Oaks, the ages of which must be calculated by centuries. These truly colossal trees, produce the grandest kind of landscape effects, and, combined with the picturesque dips and rises of the ground, furnished Mr. Hewitson with material for the formation of one of the most exquisite stretches of pleasure garden to be found within thirty miles of London; and he has not neglected his opportunity. Of dips and slopes there were abundance, and also water; but the soft undulating surface lines, here and there wanted crispness and emphasis to complete the picture, and the rock-work, destined to supply the deficiency, was constructed, under the supervision of the proprietor, by Mr. Marshall, of Liverpool, who has utilised the materials confided to him with great ability. These "materials," so to speak (namely, the pieces of stone with which the pseudo-natural rocks had to be built up), were the weather-worn stones resulting from the demolition of old Kew bridge, which, in their new position, with the worn portions skilfully turned to the front in the formation of simulated natural rock, produce the happiest

ARTIFICIAL ROCK-WORK IN OATLANDS PARK.

possible effect; and thus the rocky faces of the ravines excavated near the lake, and into which the water of the lake has been conducted, appear to be as natural as if Nature herself had provided them. The sowing of Foxgloves and Stachyses on the rugged portion of these banks, and the planting of Aquatic Irises on the edges of the water, impart wonderful naturalness to the scene—in which Furze, Bilberry, Heather, and other plants of wild original growth have been allowed to remain undisturbed, with the best possible results; while the common Bramble plays a conspicuous part in completing the natural aspect of the scene. These Brambles are allowed to trail far and wide, stretching in many places their far-reaching growth over the mown turf; and Mr. Hewitson has oftentimes desperate struggles with his garden assistants and labourers, to prevent them from lopping off these impediments to the action of the scythe, which, in some cases, is still preferred to the mowing machine. As a whole, these grounds are a perfect model of landscape composition, and are well worth a visit from every lover of the beautiful in garden scenery.

H. N. H.

THE VITALITY OF SEEDS.

A BRIEF report—taken from one of our local papers—of a lecture, delivered by me at our Philosophical Society, on seeds, which appeared at page 386 of THE GARDEN, contains a slight mistake, which I should like to have corrected. In the latter part of the paragraph I am made to state that, "To retain vitality in seeds four things are required, namely, moisture, heat, air, and electricity," whereas it ought to have been, that these requirements were necessary to stimulate the embryo into vital activity. When confined to our local papers I scarcely considered it necessary to make the correction, but, when quoted by you, I am sure you will permit me to set the matter right. The more so, as I purpose making it a text whereon to offer a few remarks of a more technical and extended character than would have been justifiable in one of our Saturday afternoon lectures at the museum, having a direct bearing on the capacity of seeds to retain intact the vital principle through an almost unlimited period of time. Before doing so, it may not, however, be out of place if I say a few words on the value of a movement inaugurated by our Philosophical Society, about a twelvemonth ago, of opening, at a mere nominal charge, their museum to the public on Saturday afternoons, and associating therewith a popular conversational lecture upon some one of those various branches of science of which illustrative specimens are found in the cases. The Saturday half-holiday now so general amongst the "working classes"—or what might be more appropriately termed the "wage classes"—and the more general recognition of the various branches of science, in connection with the education movement throughout the country, appear to my mind to call for a similar movement on the part of every institution that possesses a museum or other means of popular instruction. A few of our large provincial museums are continuously open to the public. To those I would suggest the additional attraction and enhanced value, from an educational point of view, which would attend the delivery of a series of lectures, and for which no more fitting occasion can be selected than the Saturday afternoon. The seeds of scientific knowledge thus sown are sure to find in some of the hearers all the essentials necessary for their future development; and the grain thus scattered will, without doubt, return in some shape or way, with bounteous increase, its harvest contribution to the national store-house of knowledge. But to my subject—seeds and their power of retaining their vitality when embedded deep in the bosom of mother earth. Few observers of Nature but must have met with instances where the correctness of the above statement is fully confirmed. In my younger days, when I had more leisure for botanising than I have now, nothing used to please me better than to come across a new made railway cutting or a quarry or gravel pit, where, in the newly disturbed sub-strata, there is almost sure to be found some plant or other that is, if not always new to the locality, at least but rarely met with. One or two marked instances I may specially mention. Many years ago a new siding was being made on the Great Western line, the soil for which was removed from a cutting some 30 feet deep and about six miles distant therefrom. On this siding I observed a Composite plant of an aspect sufficiently distinct to induce me to get out at the station and retrace my steps, when, to my surprise, I found an abundance of *Borkhausia fetida*, a plant of rare occurrence and unknown in the locality—confined entirely to the recently-introduced soil. My next object was to learn the source from whence the soil was obtained; and there in truth was the plant again growing profusely, but

confined to one side of the line only, that from which the soil had been recently removed; the long sloping bank opposite did not present a single specimen of it for at least a mile, which was as far as daylight permitted my investigation to extend. That these seeds came from the fresh upturned marly clay soil was fully confirmed by a nice crop of plants I raised from a portion of the soil I took home with me. Another instance of more recent date occurred in the cutting between Bridlington and Scarborough, where *Iberis amara*—our British Candytuft—was developed in abundance, both in the cutting itself and on the embankments formed of the soil removed therefrom, and where it holds vigorous possession to the present day. This plant was, I believe, thus restored to the Yorkshire flora. Still more recently, as the result of an embankment made from a cutting about 18 feet deep, the following season I found a considerable sprinkling of *Delphinium Consolida*, a plant quite foreign to the locality, and one whose indigenous character is doubted by many. Two or three other plants of minor interest occurred that were also new to the neighbourhood. A further illustration, that has a similar bearing on the matter, may be noted. A pond of considerable size in this neighbourhood, that has been dry for two years owing to a general lowering of the springs, has been covered this season with an abundant crop of a species of *Chenopodium*, which, though not absolutely absent in this part of Yorkshire, is of exceedingly rare occurrence. The foregoing are all from my own observation, and I find recorded in this week's *Athenaeum*, amongst "Physical Notes," a valuable corroborative testimony from Professor Von Heldreich, of Athens, who states that on the removal of the mass of slag accumulated in working the Laurium Mines, some 1,500 years ago, which is now being worked over again for the sake of the metal it still contains, quantities of a species of *Glaucium* or Horn Poppy, has made its appearance, and, what is more, it proves to be a new and undescribed species, to which the name *Glaucium Serpieri* has been given. In the former instances no idea can be formed as to the probable length of time the seeds thus disinterred and revived have lain in their dormant state; but, in the latter, tolerably well authenticated history carries the date of the super-imposed heap of refuse to between 1,500 and 2,000 years ago. Doubtless the absence of air, an equable and unvarying condition as regards moisture and temperature, and, above all, the complete neutralisation of the physical influence of the sunlight, whether in its electric or actinic character, or in both combined, caused by the distant removal of the seeds from the surface—appear to constitute the means by which Nature exercises a preservative power in seeds as astounding as it is interesting. I may further state that from my experience, with but one exception, that of the Candytuft, these resurrection plants—if I may use the term—are but short-lived in their new localities, and rapidly succumb to the more vigorous vegetation, which may possibly have been absent in the past, but has become developed in the present, as a result of those terrestrial mutations that are in continuous progress in Nature; and, as a matter of course, are more intensified where Art and civilisation have contributed their special quota of disturbing influences.

JAMES C. NIVEN.

Hull Botanic Gardens.

A FLOWER MISSION.

FIVE or six years ago a young girl, at that time a teacher, noticed in her daily rambles the great waste of fruit, and especially of flowers, in the gardens of the wealthy. Myriads of blossoms that might gladden sad hearts and tired eyes, are allowed to fade through the long summer days, sometimes because their owners are absent abroad; oftener still because of the super-abundance resulting from liberal culture. Each week our thoughtful girl came into the great city, always bringing with her a basket or a bouquet of fresh flowers, sure, even on her way from the station to her home, to be asked for flowers by a score or more of little children, ragged, yet with the love of the beautiful in their hearts. The summer passed away, but not the happy thought born of the summer. In the city are vast numbers of poor suffering souls, not alone in hospitals and on sick beds in narrow, straitened homes, but hundreds of sewing girls spending their lives in hot stifling work rooms in the heavy woollen manufactures, for fall and winter trade. Where is their summer? What do they know of Nature's gracious bounty in field and wood, on hill and glade? On the one hand the need, on the other the demand, and its possible fulfilment. Not only in the fields and woods, ready for the harvest, but also in the conservatories and greenhouses, and gaily blooming flower beds of the suburban gardens environing the great metropolis, are countless superfluous blossoms that were not born to blush unseen, and should not waste their sweetness on the desert air. The first Sunday in May, 1869, in several of the city churches a brief notice was read, inviting all having either fruit or flowers to spare, or

time to gather wild ones from the woods, to send their gifts to the chapel of Hollis Street Church, which would be open on Monday and Thursday mornings from eight till twelve for the reception and distribution of flowers and fruit to the sick and poor in the city. Any and all who might have leisure and inclination to assist in tying up bouquets, or in carrying them to their destination, were invited to meet at the chapel on that Monday morning; a curious example of an organisation almost self-created; entirely composed of volunteers; no membership or qualification for membership other than the desire to lend a helping hand; no president, no official red tape: each did that which seemed right and fitting, and in keeping with the beauty and fragrance which, week after week through the long summer, made the old chapel blossom like the Rose. We quote a few words from an account of that first day's experiment: "The first to come were two girls, who, glowing with the air of their country homes, and excitement from the thought of the pleasure they had the means of giving, appeared with baskets filled with *Houstonias*, *Cowslips*, *Violets*, and *Anemones*, nicely tied up in pretty bunches; then two more, with baskets full of *Violets*; and again another with field flowers. So far all were personal friends; the next contribution, however, was from a stranger—hot-house flowers, and ripe red *Strawberries*. Again a silver wedding gift, of twelve beautiful bouquets, seeming to the donors the pleasantest memorial they could convey of their own happiness. Again a Lady Bountiful sent her carriage laden with cut flowers, pot plants, and branches of flowering shrubs, placing her carriage also at the service of the members—a welcome gift indeed, for it is no light task to carry the large, flat, flower-laden baskets to their destination." This was a good beginning for such a quiet, unostentatious charity: contributions from thirteen sources; distributions to 150 persons. The work begun under such favourable auspices never flagged throughout the summer. The givers were liberal; the workers also. School children in the surrounding towns made excursions to woods and fields, and sent in generous collections of wild flowers, Mosses, and graceful Ferns. Regular contributions were also sent from private conservatories, sometimes carefully and tastefully arranged in little bouquets, ready for distribution, sometimes in huge bunches of individual flowers, easily separated; sometimes a large basket held many varieties of flowers in layers, with moist cotton between; the flowers having been sorted in the gathering, the *Pinks*, the *Roses*, the *Heliotropes*, &c., which rendered the work at the chapel much simpler, and lessened greatly the risk of breaking the stems, always to be feared in separating indiscriminate masses. The essentials for work in the chapel were a long table, broad enough to turn the flowers out in heaps, with room for assorting; shallow tanks of water in which to place the bouquets as fast as prepared until the hour of distribution; plenty of string, and scissors, and chairs. It is unwise to attempt to work standing; the fatigue is great, and should be lessened as much as possible. Large flat baskets, like market baskets, are the most convenient for carrying the flowers without injury. It seemed as though everyone had been waiting for just this chance; for not alone were the flowers provided, and busy, willing hands to arrange and distribute them, but corporations (supposed to be soulless) became liberal and generous to an unwonted degree. Railroads transported free of expense, the baskets and parcels for the Flower Mission; not only over the roads, but always finding among the *employés* at the stations some one to carry them to the chapel. If the baskets were marked with the owner's name and residence they were returned also by the next train free of charge. Many a basket twice a week made its journey to and fro in this way from Dedham, Newton, Wellesley, Hingham, Lexington, and even as far as Plymouth. From Quincy twice a week came two or three huge wash-tubs full of garden flowers and wild flowers. In the gathering every one united, Catholic and Protestant, orthodox and Unitarian, all for the love of God and His children. We copy a few statistics from the report of the ladies connected with the Flower Mission at the close of the first season, in October, 1869:—

Contributions in flowers	356	Number of towns sending contri-	
" " in plants	30	butions	26
" " in fruit	30	Number of bouquets distributed..	6,715
Number of contributors	106		

Of these 1,132 were sent to people confined to the city during the warm weather. The plants were scattered among various homes. The remainder of the flowers were taken to the hospitals and asylums, and sometimes to the gaol and State prison. In the spring of 1870 the ladies of Cambridge proposed to co-operate with the Hollis Street Chapel by establishing a branch mission for the distribution of surplus fruits and flowers in their vicinity. In 1871 Chelsea followed suit. Thus the country was brought to the city—close to thousands who are never permitted to "go a-Maying," or to look upon the full glory of summer time. During the second year of the mission the contributions, and consequently the distributions, were more than doubled. Over 11,000 bouquets were distributed, besides 1,800 pond Lilies, chiefly from one

friend. These last wrought a "special work of grace" among the denizens of the North End, to quote the words of the resident missionary in that apparently godless region. There were men, and women too, whose hearts seemed like nether millstones, impervious to all good influences, baffling every attempt at sympathy or enlightenment, to whom the sight and smell of the water Lilies brought tender memories of childhood perhaps, when, young and innocent, they too had gathered the pure white blossoms. The Lily brought to them its message of beauty, grace, and sweetness, rising above the waters, reaching heavenward even from the black oozy depths below. Who shall say that some human heart to-day is not purer for the silent lesson of those Water Lilies? Beauty, the gift of the All-Beautiful as well as the All-Bountiful, is an evangel for ever to human hearts. Surely they need it most whose lives are rendered the most unlovely by sin and misery. It would be pleasant to give the name and the portrait of the Pansy Man; but the modesty and reticence which so long kept him unknown, save by the sobriquet earned by his lavish gifts, forbid. Literally by thousands were they brought, royal in purple and gold, and every rich strange tint born of hybrid culture. About twenty hospitals and infirmaries were supplied week by week; and many touching incidents might be related in connection with them. It was odd to see the various preferences shown in the hospitals. The men would oftenest choose bunches of fragrant border *Pinks*; the women almost always wanted *Roses*; if country bred, wild flowers were the most eagerly sought. In the work-rooms, garden *Roses*, sprigs of trailing *Arbutus*, sweet *Honeysuckle*, or boughs of pink-tinted *Apple blossoms*. As the weeks wore away, and a kind of intimacy grew up between givers and receivers, special cases were remembered in the making of the little bouquets: to the blind girl always as many fragrant flowers as possible; the consumptive, in the clean white hospital bed, welcomed the scarlet *Geraniums*, which lent a bit of warm bright colour to the prevailing white of the wards; one young sewing girl always begged for Lilies of the Valley—it seemed easier, she said, to sow the long white seam with the delicate white flowers keeping her company. The report of the physicians connected with the hospitals is most encouraging. They say it is a great aid to convalescence when the patients have something to divert their thoughts from their own suffering, and nothing answers that purpose so well as the fresh beauty and fragrance of flowers. In Chelsea many of the physicians send in lists of special cases in their practice where such gifts would be particularly beneficial: oftentimes they say the fruit sent is the best of agents in hastening recovery. Among the pleasant records of the mission are the visits to the Bennett Street Dispensary, where many poor sick people go for advice and medicines—often 200 patients in the course of the day, each waiting their turn, and weary waiting it is. The surprise and delight manifested when the flowers are distributed among them must be seen to be appreciated. Many touching letters have been received from hospital patients and from the work-rooms. A brief extract from one of the latter is given:—"I think our Heavenly Father must have put it into some sympathising Christian heart to thus remember the toiling ones. We who are shut up from morning till night, and see but little of Nature's beauties. I, for one, very deeply appreciate the gift of flowers. As I looked at them I thought, 'What is the message they have brought me?' Something within me seemed to say, 'To comfort you, to whisper hope whenever your faith grows dim!' Christ must have loved flowers, for He gave a lesson to His disciples, 'Consider the Lilies.' I have been considering them all the afternoon. These flowers shall fade, but the Great Master speaketh to me, and saith, 'Go, say kind words and do kind deeds to your fellow men, and cause beautiful flowers and love and trust in God's goodness to grow up and blossom in their dreary pathway, and remember that whatsoever ye do unto the least of these My brethren, ye do it unto Me. . . . I thank the mission for the flowers. They did me a world of good, turning my thoughts from the daily drudgery of life to something nobler and better. With the gratitude of a weary, toiling sister." One thing of special note in connection with this Flower Mission is that none having put their hand to the plough seem to look back or loose their hold. Sooner or later we trust every town and city, every country village, will have its Flower Mission.—*Hurper's New Monthly*.

Water-edge Plantations.—Unless in the case of very large pieces of water, where there is plenty of room for occasional clumps of trees, or where shade is an important object, plant sparingly near the water's edge. Nothing is gloomier or more depressing than a piece of water nearly surrounded by large trees which intercept the sunshine, and whose dark shade is reflected back from the water. A pool of moderate extent, with a few pendulous trees, and still fewer tall trees, sparsely scattered along its edges, leaving ample room for a broad expanse to freely admit the sun's rays to play upon its surface, is a beautiful object.—A. MONGREPIEN.

GARDEN STRUCTURES.

ICE-HOUSE AND COOL-CHAMBER.

The principal requisites for an ice-house with a cool-chamber below it for milk or fruit are, a locality where the ice can be conveniently placed in the upper part, and where there is drainage to carry off the waste from the ice. A hill-side is the most convenient position for such a house. The method of construction is the same as for any other ice-house, excepting in the floor. The walls are double, and are filled in between them with sawdust or other non-conducting material. The roof should be wide in the eaves so as to shade the walls as much as possible, and it will be found convenient to have a porch around the building, on a level with the floor of the ice-house. The floor of the ice-house must be made not only water-tight but air-tight. If a current of air can by any means be esta-

Fig. 1. Interior of Cool-chamber.

blished through the floor of the house, the ice will melt away in a very short time. A double floor of match-boards, tarred at the joints and between the floors, should be laid. The joists are placed so that the floor slopes from both sides to the centre, to collect the waste water from the ice; a channel is made along the centre to carry it to the side of the building, where it is made to pass off by means of a pipe with an S curve in it, to prevent access of air. Or the pipe may be brought down through the lower chamber and made to

one dollar for each ice-house, and it is therefore practically public property. The ceiling of the lower chamber is made to slope, as shown in fig. 3, and may be covered with sheet zinc. Above the ceiling there is the usual non-conducting layer, and a floor sustained by the usual joists, upon which the ice is packed. The coldness of the ceiling causes the moisture of the lower room to condense upon

Fig. 3. Mr. Rankin's Cool-room.

it. This moisture runs down the slope, and drops into troughs or gutters of zinc, which are suspended beneath it. From these it is carried off into the cistern, which collects the waste water from the ice above. Such cool chambers as either of these may be used to preserve fruit, meat, vegetables, or other perishable substances. Some ventilation and circulation of air in them is necessary to prevent mould or mildew, and it would be preferable to build the lower story of brick or stone rather than of wood. The upper part of the building could be built of wood as well as of any other material. A temperature of 40° has been maintained in such a chamber throughout the summer, but this can only be done where the soil is very dry and gravelly. The elevation of the building is shown in fig. 2.

WOODEN CURVILINEAR CONSERVATORIES.

MESSES. FLETCHER, LOWNDES, & Co., who object (see p. H5) to wooden curvilinear conservatories, are, I believe, manufacturers of curved conservatories in iron, and therefore can hardly be considered to be disinterested parties. They state that a wooden conservatory was erected in Birmingham in 1872 by a well-known firm, which proved a failure; but of this house I know nothing, having neither seen it nor heard of it; but, admitting that such a failure did occur, it proves nothing against my house erected at Croydon. Your correspondents are evidently unacquainted with my houses, for they go on to speak of the objections to be urged against tie-rods, trusses, and iron columns, from all of which my houses are free. The house erected by me for Mr. Ley is 52 feet long and 22 feet wide, without reckoning the porch, which is 21 feet high to lower side of lantern, and 42 feet high over all. The curved bars are 12 feet long, and only 3 by 1½ inches in section. The inside space is quite clear—no cross-ties, columns, or wooden trusses whatever. The lantern and tower are carried entirely by the bars, and I am quite sure that Mr. Ley will be pleased to show it to anyone who may desire to inspect it. But, it may be asked, how long will such a house last? Well, to that question, I think I can give at least a partially satisfactory answer. I erected a house in the Royal Horticultural Society's Gardens in 1871, the bars in which were bent on my patent principle; it has only just been taken down, and I am now re-erecting it. Now, although this house had been nearly four years in existence, not a single square of glass in the roof has been broken, or even cracked, although the house is without ties, columns, or wooden trusses, and the glass is bent, and every one knows how brittle bent glass is. I make no claim as regards novelty in using straight glass on bent bars; I believe it is a hundred years old, and I have no doubt that plenty of your readers have old conservatories glazed on that principle. The roof of the office in which I am writing is glazed in that manner, but it is only done for cheapness, and it lacks that full and round appearance, which bent glass alone can give; the only point to be considered is, whether the extra appearance is worth the extra cost. Mr. Baines, I see, deprecates the use of yellow pine for houses. I never saw or heard of yellow pine being used in that way; it is a Canadian wood and the most expensive deal we have. He advocates red deal, or yellow deal as it is called in London; this is a Baltic wood, and I think he will find that it is the wood which all horticultural builders use; I know of no exception, and this is the wood of

Fig. 2. Exterior of Ice-house.

discharge into a cistern, in which the water is kept always a few inches above the level at which it is discharged from the pipe. The method of this arrangement of the floor is shown at fig. 1, which represents a section through the floor and lower chamber, in which the shelves are seen. Fig. 3 shows the patented arrangement of Mr. Rankin, of Denison, Texas, and Emporia, Kansas, which he has adapted to the refrigerator cars, in which fresh beef is brought from Texas to the Eastern markets. Although this is patented, Mr. Rankin makes no charge for the use of it, except the nominal one of

which old houses, as far as I have seen, are all made. The main cause of decay in houses is unseasoned wood. If wood, when painted, is damp in the centre, the moisture, being sealed in by the paint, soon produces decay. Houses built with heavy timbers are more liable to decay than lighter houses, as the chances of thorough seasoning are in favour of the smaller wood. Mr. Baines's praise of iron houses rather surprises me; for if there is one subject on which I have found all gardeners to agree, it is their condemnation of iron houses; even Messrs. Fletcher, Lowndes, & Co., who are iron-house builders, say: "We are no advocates for iron in the construction of horticultural buildings." W. LASELLES.

Bunhill Row, Finsbury.

THE FRUIT GARDEN.

CULTURE OF THE RASPBERRY.

THE Raspberry is a moisture-loving plant, found wild plentifully in the northern counties in moist and shady places on the outskirts of woods associated with Foxgloves and certain varieties of the Dog Rose, a circumstance which furnishes a clue to its cultivation. The best plantation of Raspberries we ever remember to have seen, occupied a low-lying quarter somewhat shaded by large trees, which grew at some little distance off; the soil was a deep moist very sandy loam resting on pure sand. The canes were extremely luxuriant, running up straight and strong. Such a situation should always be chosen, if possible for Raspberries. A north border answers very well in the south, but is too shady in the north. The space behind north walls, however, is too limited and valuable for summer crops to be devoted to Raspberries. Where there is no choice, the best must be made of any open quarter at command; and much can be effected by means of good management. The first consideration is well-trenching the soil to the depth of 2 feet at least; for although the Raspberry is a shallow-rooting plant, yet deep trenching is advisable in order to aerate the ground and make the surface sweet. If the land is at all heavy, a liberal dressing must be given of any material which will have the effect of lightening it—such as lime-rubbish, burnt clay, sand, leaf mould. We have used sifted coal-ashes, mixed with manure bountifully, on heavy clay with the best effect; and with annual top-dressings of the same, the roots will soon abandon the clay and spread themselves among the top-dressing like a mat. Though the Raspberry will make very luxuriant growth under favourable circumstances, we do not think it advisable, as with other fruits, to give it much room; planting in rows 4 feet apart each way will be sufficient. The roots do not wander far from the plants, which, when close, shade the soil and protect them from the heat of the sun; and the annual top-dressing maintains its vigour better than when the plants are allowed more room. We annually wheel in amongst our Raspberries, and other small bush fruits, unlimited quantities of short Grass from the machine-mowings of lawns; it shades and keeps the soil moist, prevents the growth of weeds—for it must be remembered that this Grass contains no seeds of weeds—and finally it is dug into the ground with more manure in winter. Various plans are adopted for the support of Raspberry canes; but the best which we have tried is training them in the form of fans to wires, stretched along the rows espalier fashion, from posts at either end, the fruiting canes being trained right and left, leaving the centre over the stools open so as to afford room for the young canes in summer. Arching the canes rainbow fashion and tying the tops together is another mode of training often practised, and it has the advantage of not requiring any stakes; but it gives birds great facilities for getting at the ripe fruit, and bundling the canes together is always objectionable. Tying the canes in bundles to upright stakes is also to be avoided, inasmuch as there is not sufficient room for the development of the young canes and the fruit-bearing shoots together, and this bundling system is not favourable to a proper circulation of air among the ripening fruit. The espalier system of growth is much to be preferred, as it allows room for the fruiting branches to extend right and left, they receive an abundant circulation of air, the young canes have room to grow, and, finally, the fruit can be gathered with facility. The best Raspberries with which we are acquainted are the Red and White Antwerp, the Fastoff, and the Sweet White Antwerp. The autumn Raspberries—October red and yellow—unlike the common summer kinds, are of a drooping straggling habit, and partake more of the habit of the Blackberry or Bramble than of the Raspberry. They require a dry warm situation, in order that they may ripen off their fruit in a season when there is much rain and occasional frosts. They are more slender in habit than most of the summer sorts, and like the Bramble fruit on the current year's growth from the stool; they should, therefore, be entirely cut over early in spring. The Bramble

finds support on hedgerows, or on anything which may be near it, and autumn Raspberries must also have some support, else they get broken by the wind. A good plan is to drive in three strong stakes round each stool, and to fix them together at top by means of a wire or wooden hoop; spread out the canes and regulate and tie them to the hoop or wire, letting them hang over to the outside. All weak growths should be pulled up in summer, leaving only six or eight of the strongest. These autumn Raspberries must not be expected, to equal in flavour the summer varieties, nor are they so large as the Red and Yellow Antwerp. They are, however, very prolific, and come in to help the dessert and the cook at a time when small fruits are scarce. Raspberries may occupy the same situation for years in succession, and yield good crops where the soil and climate are favourable; but, in many instances, especially on dry soils, it will be necessary to renew them frequently, if strong growth is to be maintained, and, consequently crops of fine large fruit. The Raspberry has a tendency also to spread, and the stools get ragged and worn out. In forming new plantations, the strongest suckers should be carefully lifted and transplanted into nursery lines for a season, to gain strength and make roots and buds at the bottom, and the following season, when ground has been trenched and prepared for them, they may be finally planted. Old plantations will be much improved by having the soil dug away from around the stools up to the points of the roots, and also by shaking away the soil partly from the roots, and substituting fresh rich soil, spreading the roots well out in it, and afterwards well mulching with rotten dung. The canes of Raspberries should not be pruned or shortened until the wood has ripened and the foliage fallen; and there should be no deep digging between the rows, so as in any way to injure the roots.—*The Gardener.*

Cutting and Storing Grafts.—There is no better time to cut grafts than at the commencement of winter. In cutting and packing them away, there are some precautions to be observed. In the first place, let them be amply and distinctly labelled, as it is very annoying to find the names gone at the moment of using them. For this purpose they should be tied up in bunches, not over 2 or 3 inches in diameter, with three bands around each bunch—at the ends and middle. The names may be written on a strip of Pine board or lath, half-an-inch wide, a tenth-of-an-inch thick, and nearly as long as the scions. This, if tied up with the bunch, will keep the name secure. For convenience in quickly determining the name, there should be another strip of lath, sharp at one end, and with the name distinctly written on the other, thrust into the bundle with the name projecting from it. If these bunches or bundles are now placed on end in a box with plenty of damp Moss between them and over the top, they will keep in a cellar in good condition, and any sort may be selected and withdrawn, without disturbing the rest, by reading the projecting label. We have never found sand, earth, sawdust, or any other packing substance, so convenient, clean, and easily removed and replaced, as Moss, for packing grafts. It is needful, however, to keep an occasional eye to them, to see that the proper degree of moisture is maintained—which should be just enough (and not a particle more), to keep them from shrivelling. They must, of course, be secure from mice. Plum grafts, which are sometimes injured by intense cold, are generally better if cut before the approach of the severest weather and securely packed away.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Galvanised Wall Stnds.—We have received from Messrs. Reynolds, of New Compton Street, Soho, samples of the kinds of studs which they make for wiring walls. They are made of galvanised cast-iron, with an eye in each, through which the wire passes, and in appearance are much neater than the wrought-iron eyes mostly in use for that purpose.

Twelve Good Pears for Walls in the Midlands: OAKLEY. The following is a selection of twelve good varieties:—Jargonelle, Louise Bonne of Jersey, Thompson's, Fondante d'Automne, Comte de Lamy, Maréchal de la Cour, Beurré Bosc, Doyenné du Comice, Glou Morceau, Josephine de Malines, Marie Louise, and Beurré Diel.—C.

Pruning.—It is said that the donkey first taught the art of pruning the Vine; man being merely an imitator, after seeing the good effect of thus cropping the points of the young shoots. It is not always the greatest wisdom to originate, but to turn to good account whatever by thoughtful observation comes within our reach.

Effect of Dry Summers on the Flavour of Pears and Apples.—Dry summers appear to give Pears and Apples flavour, but not size. Here Pears are delicious. Marie Louise and Louise Bonne of Jersey are excellent; and Beurré Diel, not generally good, is, this season, much better than usual. Beurré Hardy, Beurré Bosc, and Fondante d'Automne, just over, have one and all been truly grand in flavour, but not over large. Among Apples, King of the Pippins is a bright star, being handsome in appearance and good in quality; Ribston Pippin, yet the King of dessert Apples, are also fine this season. Pear-good's Nonesuch, which I have likewise seen, may be described as an improvement upon our old favourite, the Blenheim Orange, and if it bears in a young state, which it promises to do, it will certainly drive Blenheim Orange out of the market.—STAMFORDIAN.

THE KITCHEN GARDEN.

A PARIS MARKET GARDENER ON SEWAGE MANURE.

EVERY time that we visited the ground of the sewage garden at Clichy we were struck with the difference between the crops there, and similar crops in market gardens. The vegetables appeared to be only half the size of ours. It was the same in the case of field crops, and especially with the Beetroot and Maize. The season was moist, and, from the nature of the experiment, the manure was moist; we did not, therefore, form any opinion with respect to the value of the sewage. In 1868 the engineer-cultivators of Clichy were favoured by an exceptional summer. In that year they could compete with the best market-gardens in Pumpkins and Cardoons. But is there anything surprising in that? What these plants require is plenty of sunshine above, and plenty of water at their roots. Their salads, although apparently flourishing when young, had almost all damped off when gathering time came. The Cabbages were only a very moderate crop. The Leeks and Carrots the same. The Tomatoes were a short crop; the fruit was tolerably good, but ripened very late. The Melons planted out perished to the extent of three-fourths, and the remaining fourth was only saved by the exceptional heat of the summer. The White Celery was satisfactory, but the Celeriac was not. There was a very fine field crop of Maize; but the year was unusually favourable for this crop. The Beetroot was very inferior to that grown in the plain. The Potatoes were for the most part lost, but then it was a bad season for them nearly everywhere else. The badly-formed and strange-looking tubers, and numerous deformities of growth proved that the mode of culture employed had been unfavourable to them. The following are some of the most important of our observations:—On a space of 42½ square feet, we counted twenty tufts of French Beans—in a market-garden there would be forty to forty-five tufts in the same area. On a similar area were eighteen plants of Celeriac—in a market-garden there would be forty-eight plants, double the size. On a similar area were twenty plants of White Celery—in a market-garden there would be fifty-six plants, certainly finer. On a similar area twenty-four plants of Endive—in a market-garden there would be forty-eight. On a similar area eight heads of Cabbage—in a market-garden there would be thirty-six; and so on with all the other crops. The half of the ground is lost in the channels. It is impossible to make sowings and inter-plantings among the plants grown in this way, and yet the produce is only very indifferent in size and development. It is only at the distance of 15 or 20 leagues from Paris that these sewage crops could compete with those of the market-gardeners at Amiens. As for the Parisian market-gardeners, these experiments have taught them nothing worth knowing, unless it be the fact that they are still the most advanced men in their business, and that in this so much extolled sewage manure they will find nothing worth adopting. The field crops at Clichy did not offer a more encouraging prospect; on an area of 94 square feet we reckoned eighteen plants of Maize where there should have been double the number. On a similar area we counted twenty-one very middling plants of Beetroot. In the plain this space would be occupied by, at the least sixty-three, and at the most eighty-one plants, with finer roots and of better quality. All the other crops there called for similar remarks. Supposing for a moment that the plants grew as well at Clichy as they do with the market-gardeners, would the latter be able to draw any profits from their land, rented at from £24 to £30 an acre, if they grew their plants with such spaces between them? Assuredly not. Since the engineers have done so badly in an exceptionally good soil and an unusually fine season, the market-gardeners will, for a long time to come, stick to their good horse-mannure.

Origin of Guano.—It has generally been believed that guano was composed entirely of the excrement of birds—the accumulation, perhaps, of centuries. Recent discoveries, however, have satisfactorily proved that birds are not the sole instruments of its production. Dr. Hahel, an American, has devoted many years to microscopic and chemical experiments on guano; and he has proved with certainty that it contains fossil sponges, and the debris of marine animals and plants. It is well known that, in the neighbourhood of the Chinchas, and other guano islands, the anchors of ships have brought up this substance from the bottom of the ocean. From these facts, and others equally interesting, Dr. Hahel concludes that the deposits of guano are the result of accumulations of fossil plants and animals, whose organic matter has been changed into an azotic substance, the mineral part remaining intact. The rapid consumption of the guano beds of Peru renders this subject an important one; already, in America, artificial guanoes are manufactured, which are principally composed of the refuse of fish.

A scientific commission, named by the Peruvian Government, to enquire into the position of the guano beds, announces the discovery of considerable quantities of it on the mainland. The ancient Peruvians were well acquainted with the value of these mines of wealth, and numerous traces are found of their having worked them. At Pabellon de Pica, it has been estimated that one bed alone contains six million tons, that the island of Lobos de Tierra would furnish two millions, and that in other situations a very large quantity of guano might be obtained; some of it, however, being of inferior quality. Some of the beds are from 60 to 90 yards in depth. They are covered by a stratum of chalk. There is no doubt that the Peruvian commission will be able to throw some important light on the origin of guano.—W. N.

Purslane in Paris Market Gardens.—Of this herb, two varieties are cultivated, viz., the green and the yellow. It is sown in January in a hot-bed under a frame, no other crop being sown along with it. The crop is cut with a knife, and the bed being immediately afterwards trimmed and cleaned, and the walks made over afresh, a second crop may be gathered. It is also sown in the open ground from March to August. In summer it is sown in a shady place. A few seeds may be sown in open beds among other plants fond of water, but the Purslane should always be pulled up before these are incommenced by it. It is always better, however, to sow it by itself. Each sowing should have a good covering of spent manure, and, as the seed is very small, it should be mixed with soil to avoid sowing it too thick. Seed is obtained by allowing some of the plants sown in spring to run. It should be gathered a short time before it is completely ripe, otherwise, from its smallness, it is liable to be lost. It will keep good for eight years. This plant is eaten either as a salad, or cooked.

The Potato Crop.—In this locality, early kinds of Potatoes, that escaped the late spring morning frosts and long duration of cold weather, paradoxical as it may appear, came into use earlier than in any previous season, thus showing that anything that checks the growth of stalk and foliage, so long as it does not actually kill them, favours early tuberization and good quality. The second earlies, and, indeed, all such crops as had finished growth by the middle of August, were both good in quantity and quality. All the later kinds, however, hereabouts, left growing or in the ground after the first week in September, have been much damaged by disease, and are, to a great extent, making a second growth, rendering them still more worthless; and the latest kinds of all left in the ground till October, have been almost a failure; indeed, to a large extent, not really worth taking up. I never saw Potatoes worse. A hard working industrious man, who had planted about 8 acres, mostly late kinds, told me that he was ruined through the failure of his Potato crop this season. When he commenced taking it up in the first week in October, he did not get one bag of good or sound Potatoes to ten diseased.—J. BARNES, *Ecmouth.*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Christie's Self-protecting Broccoli.—This is the best self-protecting Broccoli with which I am acquainted. It is of the finest quality and very hardy, coming into use in March and lasting to the end of June. My stock of it came from a seedsman in Hull.—RICHARD NISBET, *Asenbury Park.*

Veitch's Autumn Cauliflower.—Let me add to what has already been said in favour of this Cauliflower that I have grown it from the time when it was first sent out, and found no difficulty in obtaining handsome heads of it in autumn, a season during which good heads of Cauliflowers are invaluable.—D. S. GILLET, *Court Garden, Great Marlborough.*

The Two Best Tomatoes.—We believe it is now conceded that the Trophy is the best late Tomato, and Canada Victor the best early. Growers will do well to select for seed the largest and smoothest of these two varieties, and lay them on a shelf to ripen. While varieties may degenerate by selecting seed at random, they will also improve by carefully picking out the best of each kind.

Walker's Early Regent Potato.—This Potato has been exceedingly fine here this season. The crop is abundant; and out of a couple of tons there is not half a hundredweight of diseased ones. The tubers are very rough in the skin, which is invariably a certain indication of good quality. When cooked, they are dry, mealy, and of the best flavour. Potatoes in general in this district are a fine crop and very free from disease, but I have seen none to equal this variety.—J. MUIR, *Chaceford.*

Selected Lapstone Kidney Potatoes.—This season I have had splendid crops of all sorts of Potatoes. The American kinds, owing, I suppose, to the dry season, are drier and better flavoured than usual. But of all the Potatoes, both for crop and flavour, nothing beats the Selected Lapstone, which is so great a favourite with my employer, that he eats no other late variety. The crop of this Potato this season is perfectly astounding, and the tubers are of good shape and size.—R. GILBERT, *Barghly.*

Rampion in Paris Market Gardens.—Sown broadcast in June and July. A little soil or spent manure should be mixed with the seed, as it is very small. It is sown along with Carrots, and an interplanting may be made of Roman or Cabbage Lettices, but not if the Rampion is sown along with Rattles or Spinach. A slight mulching is given, and frequent gentle waterings as soon as the seed is up, else it will be withered by the heat. The crop comes in in February or March and continues for some time. The plants should be pulled up by the roots, as both roots and leaves are used in salads along with Corn-salad. No protection is necessary in winter, as this plant is not injured by frost. Seed is gathered in the second year from a few of the finest plants. The seed ripens in July and keeps good for five years.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

SPRING bedding plants, of all sorts, and the various dwarf and berry-bearing shrubs, recommended in former calendars to be planted out, will now be getting somewhat established in their respective beds, and all that will be required to be done for some time will be merely stirring and refreshing the surface of the beds and borders in which they grow, and keeping the surrounding turf and gravel walks as free from weeds as possible, falling leaves, worm-casts, and littery matter of all kinds. In cases in which it may not be intended to furnish the beds with spring flowers or shrubs, they may, as soon as the summer bedding plants are removed, be at once heavily manured and deeply dug; or the beds may be dug over roughly without the immediate application of manure, which should, however, be frequently turned over during the winter months, so as to be ready when wanted. Late-flowering plants, such as the various sorts of Pompone and large-flowered Chrysanthemums, when planted on borders, in front of low terrace walls, or in other situations out of doors, should, while in flower, have some temporary means of protection held in readiness for them, such as mats or frigi domo. It will be found to be difficult, if not impossible, to keep all parts of the grounds at present in thoroughly good order; and in many establishments this is neither expected nor desired. In out-of-the-way places, therefore, as well as in the immediate vicinity of deciduous trees, falling leaves may sometimes be permitted to lie until all, or the greater portion of them, are down, when a thorough cleaning up should at once take place. It will always be necessary, however, to keep lawns, walks, and drives in view of the residence, in good condition; and, in order to ensure this being always the case, it should be the appointed duty of one man (or, if necessary, more) to attend to this matter daily at an early hour. The transplanting and re-arranging of shrubs and trees, wherever such operations are considered necessary, should now have immediate attention, more particularly as regards evergreens, which are more susceptible of injury through removal than deciduous plants; in the case of these, early autumn planting is most likely to secure success, as it allows time for repARATION before the temperature of the soil has fallen to any great extent. Standards of all kinds should be at once securely staked, in order to prevent wind-waving, and the surface of the soil should be afterwards well mulched with partially rotted manure. Ground work should be pushed forward with the greatest possible despatch while the weather continues open and favourable for operations of that kind.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Roses.

Those who have beds prepared, and who wish to substitute fresh Roses for such as have died off this summer, will now be able to obtain plants in excellent condition for planting; indeed, this is the proper time for planting if a good display is to be made next summer. Before planting it is advisable to examine all roots, and with a sharp knife to remove any that are bruised or that need pruning. Plant the strongest varieties in the centre, so that, when the bed is finished, it may form a pyramid. I always plant dwarf Roses 2 feet apart, a distance which allows plenty of room for air to circulate freely amongst them. The appearance of Rose beds may be improved by having a cordon of Roses round the outside of them on wire or other supports 1 foot high; keep them neatly trimmed, and edge the whole with *Stachys lanata* or *Pinkia Sieboldii variegata*. Beds edged in this manner are permanent, and look well throughout the summer. A bed of mixed Roses, if kept in good condition, surpasses in interest all others in the flower garden, and is much more useful, inasmuch as when ordinary beds consist merely of foliage, and when we are put to our wit's end to find cut flowers enough to keep up the supply, Rose beds furnish us with what we want. Put a few pot Roses, the wood of which is well ripened, under cover for forcing. Those intended to be started first should be pruned at once so as to get the buds well up; prune out the weak growths, and cut down the strong shoots to three or four buds, according to the strength of the plant. All the pruning which Tea Roses require consists in cutting out the old flower shoots; plunge the pots in a bottom-heat, ranging from 55° to 60°, giving air during the daytime, and syringing with tepid water morning and evening.—H. G.

Kitchen Garden.

Now, when the principal sowings and plantings for this season have been completed, is a good time to determine matters respecting next year's campaign. A rough plan should be prepared of the kitchen garden, showing with what each plot of land has been planted during the past year, and indicating the rotation for the

coming season. If this is well considered now, manuring and trenching operations can be carried out with a view to the requirements of each particular crop. The plan should be drawn to a scale, in order that there may be no difficulty in determining the exact position of each crop, even though removed. It is necessary not only that plenty of everything should be provided, but that there should be no waste, and there is scarcely anything that better repays a little personal supervision than the gathering of vegetables, if a good supply is aimed at. If there is a good supply of manure too much stress need not be laid upon the rigid carrying out of any given rotation; still it is desirable to avoid, as far as possible, planting the same kind of crop two years in succession on the same land. This is a question, however, which hinges very much upon the manure supply, and its intelligent application. When a garden has to be heavily and constantly cropped, deep culture and heavy manuring must make up for any breach in the recognised system of rotation. As a rule, where much has been taken out of the land, much must be returned to it. All land intended for root-crops next season should be manured, if it is necessary, and deeply trenched as soon as it can be conveniently done, either throwing the soil up into ridges, or at least leaving the surface as much exposed to the action of the weather as possible. The manuring and digging of fruit-tree quarters and borders will be better delayed till the leaves are down, and the trees pruned, so as to avoid incurring unnecessary labour. In warm situations, if it is desired, one or two of the earliest Peas and Beans may be sown; but, considering the risk they have to run, unless attendant circumstances are favourable, it is a question whether it would not be advisable to delay such sowings till January, especially if they can then be started under glass. However, this is a question that every one must decide for himself. Remove the surface-soil from Asparagus beds; wheel on a good heavy dressing of rich manure, and replace the soil. Salt may also be freely applied at any time when growth is dormant. Horseradish should be taken up and laid in somewhere thickly, to be always at hand and easily accessible when wanted. Provide a good supply of green Tarragon, Mint, Marjoram, &c. Peas may also be sown in boxes in heat, to provide young green tops for flavouring soups, &c.—E. HOBDAY.

Indoor Fruit Department.

Peaches and Nectarines.—If the pinching and thinning of Peach trees has been well followed up throughout the summer months, little pruning will be necessary now; still, where not done, the usual winter pruning will require attention, except in the latest Houses, in which the foliage is not yet down. Ordinary fan-training is that which is most practised, and also that by which a tree is best kept in health. Severe cutting of Peach trees, especially strong branches, should be avoided as much as possible; but, if the wood in a tree has been allowed to get too thick, which is a common fault, instead of nibbling away at the smaller twigs, branches of the older wood should be cut out, always having an eye to bringing up a succession of young wood from the bottom. In young vigorous trees, care must be taken to preserve well-ripened twigs covered with buds, cutting out the green soft branches, if thinning is necessary; but they must be retained if filling up is required. Some varieties, such as Rivers's Orange Nectarine and the Pine-apple Nectarine, are of a more dense and twiggy growth; and some, as the Noblesse Peach, are more given to lengthy growth than others; consequently, more caution is required with the latter. In tying the trees, see that every shoot has room to extend itself when growth shall have commenced, else there will be confusion and overcrowding in spring. Never shorten the bearing wood of a Peach tree. In late houses the foliage will be falling fast; keep all dry, and husband sun-heat; the foliage will fall while quite green through sheer lowness of temperature and damp. I like to see Peach leaves ripen yellow, like other foliage. The wood of dwarf trees in pots, or planted out, will want thinning and tying down in order to bring the trees into shape. Some sorts yield to this treatment well, others are more stubborn. Pendulous-growing sorts make handsome trees managed in this fashion; and, with fruit hanging down to the ground, they have a fine appearance.

Cucumbers.—The moist mild weather which we are still experiencing is favourable for late autumn and winter Cucumbers, much fire-heat not being as yet necessary for them. Continue giving abundance of air, so as to keep the plants strong for winter, and husband their vigour by cropping them lightly and keeping the growth thin. Every gardener has his own favourite sort for winter. With the majority, Telegraph is perhaps the favourite; but I prefer a good "strain" of Lord Kenyon or Syon House, and there are now many strains under various names of the old, short, white-spined sort. Avoid a large body of soil for winter Cucumbers; the plants ought to have sufficient command over the soil to exhaust it, when required, of its moisture. A body of wet effete soil is poison to winter Cucumbers.—W. D., *Canford.*

Vines.—It may be necessary in certain cases to start a Vinery earlier than usual, but too great a change in this way should not be attempted in any one year. If a period of six weeks or two months earlier is desired, it is best to spread such advancement over two years. This may be effected by starting the Vines three weeks or a month earlier than last season, and the same amount of time earlier next year from the date of starting this season. Where two or three different houses are planted with varieties suitable for early forcing they should be made to come in in rotation. In this way the youngest Vines would be allowed a natural midsummer growth for a few years. Young Vines planted during the past summer should be pruned immediately the leaves are down. The principle pruning needed in this case consists in the cutting over of the main stem, which should be shortened to within from 2½ to 3 feet of the ground. Cut away, too, all small lateral growths which may have pushed underneath where they were stopped. Where supernumeraries are grown for early fruiting, they should be cut 6 or 7 feet from the base, which length will bear half a dozen nice bunches next season. Those planted last year will have made two season's growth by this time; consequently, they will now have to be treated for their third and fruiting year. If the wood made this season is very strong and well-ripened, it should be cut at 4 feet farther up the rafter than was directed last year; any weak shoot should be cut at a foot lower down, and if generally small the whole may be cut at that length. Prune all lateral shoots from these also, and the buds on this year's growth will be found to produce strong shoots and fine bunches next year; more than 4 feet of young wood should never be allowed to remain on any Vines which have not reached the top of the rafter, as rods so treated make a much more substantial growth thus restricted than when left longer. Vines fruiting for the first time this season should have their side shoots cut in to a couple of eyes, as formerly directed in the case of old ones. Where supernumeraries have been fruiting along with these they should be rooted out, if at all likely to overcrowd the permanent Vines next season. Very little loose bark will be found on any of these young Vines to remove before washing; and, as the borders will all have been recently made, and therefore fresh and otherwise in good condition, no top-dressing of any rich substance will be needed. A slight forking should be given to the surface, however, so that water may more readily reach the roots. Remove decaying berries from Grapes still hanging on the Vines, an important matter, requiring almost daily attention at this season. Black and white Lady Downes and black Alicante are the three kinds most exempt from decay, and they are the best sorts for winter supplies, either for the practical gardener or inexperienced amateur.

Pines.—The present is a very inactive time as regards Pine stoves. Where much fire-heat is confined in any house, care must be taken to admit a little air when the sun strikes the house, otherwise the foliage is very liable to get scorched when the temperature rises above 80°. Crowns, and any odd suckers of such precious sorts as smooth Cayennes, Charlotte Rothschild, Prince Albert, and any other favourite kinds may yet be propagated in 5-inch pots, and plunged in a smart bottom-heat of 90°, in order that they may root quickly. The above-named varieties do not produce suckers abundantly; crowns of them are, therefore, generally potted and grown into plants, and very good plants they make; but, as it is throughout the winter that the crowns of such are most plentifully obtained, a small corner, with a strong bottom-heat, should be reserved, in which to place them as they are produced. Give the plunging material a liberal watering when it shows any indication of becoming over-dry. This feeds the roots, and keeps the atmosphere in good condition.—J. MEIR, *Clonsford*.

Indoor Plant Department.

Ixoras and *Dipladenias*, that were recommended to be cut back last month will now have broken, and ought to be potted; the roots of the *Ixoras* should not be disturbed more than is necessary; merely remove a few inches of the surface soil, and place them in pots 3 inches larger than those which they previously occupied, using nothing but good peat and silver sand. *Dipladenias* ought to be shaken half out of the old soil, without injuring the roots more than is necessary, using good peat, not too close, and plenty of sand. Keep the plants through the winter drier than the majority of the occupants of the stove. *Allamandas*, *Clerodendrons*, and *Bougainvilleas* should now be dried off, but not yet cut back, keeping the soil quite dry, and do not submit the plants to a lower temperature than 50° at night. *Caladiums* gone to rest, or that show signs of soon being in that state, should have water withheld, and should be placed where they will have not less than 55° or 60° night temperature. Any of the stock affected with mealy bug, scale, or thrips, wash thoroughly with "Abyssinian mixture," or Fowler's insecticide; 3 oz. to the gallon will kill thrips, 5 oz. brown scale, and for mealy bug and white scale, 6 oz. or 8 oz., according to the ability of the plants

to stand a strong dressing. When the strongest dressing is resorted to, the plants ought to have all the tender shoots, if any, cut back. Where mealy bug exists, a vigorous effort should now be made, when the plants are comparatively at rest, to thoroughly exterminate it. We frequently hear it said that, when once it has got possession of a collection of plants, it cannot be got rid of; but that is a mistake. It is merely a question of time and perseverance. The moisture necessarily used in stoves causes the inside of the glass, wood, &c., soon to get coated with a dirty deposit, which should now be cleaned thoroughly off. Now, or soon, replace the old tan by new material. If a good body of it is got in now, the heat which it gives off will, during the winter months, materially assist to keep up the necessary temperature, and, consequently, save fuel. The heating apparatus should be overhauled, to see that it is in proper working order. In Fern-houses, reduce the temperature and use less water at the roots, and also in the atmosphere, than hitherto, so as to induce the plants to go comparatively to rest, which is necessary to their making luxuriant growth when expected to do so; it will also harden the plants so as to make them in much better condition for cutting, for the season is fast approaching when they are indispensable for mixing with flowers in vases in quantity. In forcing houses a moderately brisk temperature and moist atmosphere should be maintained. *Scrographis Ghiesbreghtiana*, a valuable winter-flowering plant, should be placed near the glass, syringed every five days, and plentifully watered; *Eucharis amazonica* should be plunged in bottom heat, and also liberally watered, as should likewise plants of *Poinsettia*. Young plants of *Euphorbia jacquiniiflora* should be kept as near the glass as practicable. *Justicias*, *Pentas carnea*, *Salvias*, *Heliotropes*, and similar plants, should also be brought into flower in these houses, and from thence be transferred to a cooler situation and a drier temperature. *Camellias* should be removed from the forcing house as soon as their blooms begin to expand. *Rhododendrons*, *Azaleas*, *Kalmias*, *Weigelas*, *Luculia gratissima*, *Forsythia viridissima*, *Dentzia gracilis*, *Dicentras*, and Dutch bulbs that have commenced growth out of doors under ashes, should now be placed in these houses in quantities required, but at first they should be set in the cooler parts of them.

Orchids.

This, though a dull month for most things, suits such plants as belong to the *Odontoglossum Bluntii*, and *Pescatorei* section well; most of them are now making their growth and enjoy a dull humid atmosphere, varying from 45° to 55°; such as want potting, should now receive that attention, the fresh soil being very beneficial to them. They should not, however, be over-potted, which is apt to cause the bulbs to rot. Now is a good time to pot *Disa grandiflora*, which grows well in a mixture of rough peat and manure from an old Mushroom-bed, charcoal, and sand in equal proportions. *Disas*, also, enjoy a temperature varying from 45° to 55°, and they should be syringed twice a day. *Mesospidium vulcanicum*, *Masdevallia tovarensis*, *Oncidium nubigenum*, *Odontoglossum Cervantesi* and *Rosii*, and many others likewise flower freely in a similar temperature. *Cattleyas* belonging to the *Trianae* section will now have completed their growth, and should be allowed to have as much light as possible, in order to ripen their pseudo bulbs, and thus encourage them to flower well. *Cyclogyne cristata*, *Cypripedium villosum*, *Pilumna fragrans*, *Dendrobium chrysanthum*, *D. infundibulum*, *Epidendrum vitellinum* all do well in a temperature ranging from 55° to 60°, and should all be well supplied with water while growing. We have now various Orchids that bravely maintain the gaiety of the Orchid-house at this time of the year, such as *Odontoglossums* of different kinds, *Oncidium tigrinum*, *Lælia autumnalis grandiflora*, most of which are now in flower. A constant look out for cockroaches must be kept up, as, owing to fire-heat being more freely used than hitherto, they are induced to make their appearance in greater numbers; some of the many poisons recommended for their destruction may be of use, but a great many may be destroyed by spending an hour or so every evening in looking over the plants, an inspection which often prevents choice flower-spikes from being eaten off by those pests.—M. CULLEY, *Ferniehurst, Shipley, near Leeds*.

Hardy Fruit.

Of all horticultural operations, perhaps, root-pruning is the one that demands the most skill, and receives the least. Some perform it with a few chauce thrusts with the spade in the dark. They believe the roots to be somewhere within a few yards of the bole, and reason that if they cut all round within a yard or so, the roots must of necessity be cut—that is pruned. I have seen choice trees root-pruned by a very similar process. Gangs of men in twos or threes, with sharp spades, have opened trenches all round the trees, cutting all roots—fertile, sterile, big, and little—with equal severity and to equal lengths. It is worse than pruning the top on similar principles; and yet to describe a line in the air, and cut the

tops all over alike to that imaginary mark, would be considered the height of absurdity. But it would be less reprehensible than many of the rough and ready modes of root-pruning now in operation; for the roots are more irregular in their growth than the tops. The worst and the best of them are generally found where least expected; hence the importance of an examination before operating upon them. Doubtless, the uncovering of roots involves much labour and care, but root-pruning is one of those operations that had better be left alone, or done carefully. The first step that should be taken, is the uncovering of all the best roots. This work is less laborious than it seems, for most of the best roots are found near the surface; and, when these are sighted, the others may be cut away without fear of injury, and with the assurance of certain benefit. After a little experience the root-pruner will be able to remove the wood makers and reserve the fruit makers; the wood makers are mostly found under the trees. It is not needful to trace out these. They may be cut off sharply within a foot or 18 inches of the bole of the tree. To make sure of this, the entire under-surface should be penetrated through with sharp spades, and the severing of these vertical roots, and disturbance of the horizontal ones for examination, will be found sufficient root-pruning. By this mode of procedure only the worst roots are pruned off, whilst, by the more common method, it often happens that only the best are mutilated. There is one more point to be noted—the disturbance of the roots for examination, while, necessarily, a root-pruning, to some extent, is also a good substitute for it. Were it possible, which it is not, to examine roots without removing any, the mere removal of the soil and the laying of fresh hold again are equivalent to a root-pruning. This is a point that has not received the attention from cultivators which it deserves. Root examination may often supersede the necessity of root-pruning. It may answer the same purpose, and may also reveal a state of things that proves pruning not to be the remedy needed.

—D. T. FISH.

November in a Paris Market Garden.*

Break up the spent manure and form it into ridges; collect and bring fresh manure to the places where it is to be used. Make the first hot-beds for black-seeded Lettuces. These beds will be turned over in January; then make the beds for Carrots and Cabbage Lettuces. Manure the beds for Cœur de Bœuf Cabbages; make Mushroom beds; force Asparagus, Sorrel, and Tarragon. Bring out frames and lights, and wash cloches. *Sowings*.—On hot-beds: short round early Carrots along with Spinach, either sown or transplanted. Spinach, or small salad among the rows of Cabbages and in the vacant spaces intended for Melons in May; Chervil in drills; Saint Thérèse under cloches; Green Peas under frames. *Plantings*.—On hot-beds under frames: black-seeded Lettuces and Spinach; roots of Sorrel to be forced. In drills: Cœur de Bœuf Cabbages. Along the walls: Passion Lettuce. *Treatment of Growing and other Plants*.—Earth-up Artichokes; store Beetroot in the cellar. Before the 10th, plant white Celery deeply, and earth-up before the 20th for fear of frosts; frozen Celery is ruined if touched; take up Celeriac and put it in a trench under 4 inches of soil; give air to Cabbage and Roman Lettuces under cloches; re-plant Roman Lettuces at the end of the month, placing nineteen plants in the space previously occupied by twenty-four, and six or eight where there were twelve; weed and cover the plants with mats if the temperature sinks to 3° or 4° below zero. *Crops Gathered*.—Blanched Asparagus forced, green Asparagus in hot-beds, Sorrel in hot-beds, Cardoons, Carrots, white Celery, Celeriac, Chervil, Mushrooms, curled Chicory, white Chicory, Cauliflowers, Milan Cabbage, Brussels Sprouts, Broccoli, Scallions, Pumpkins, Cress, black-seeded Lettuce under frames and cloches; Corn salad, Turnips, Parsnips, Parsley, Leeks, common Beet, pink, red, and black Radishes, Rampion, Salsafy, and Scorzonera. *Special Remarks*.—No change is made in the hot-beds. The Endive, if in any way necessary, may be replaced by white Celery, and the latter by Cabbages, the Spinach by Corn-salad in the raised beds, the Corn-salad by Chicory under frames, the white Celery by Celeriac, the Cabbages by Sorrel, Parsley, or Scallions, the latter by Chives, the white Onions by Chervil, the latter by Spinach, the Chives by Corn-salad, the Cabbages by Chervil.

Tussock Grass.—Unfortunately the specimens of Tussock Grass gathered in the Nightingale Islands were lost in the fight with the penguins and grebes. I have, however, no doubt that the Grass is the same as that gathered in Tristan d'Acunha, which is a *Spartina*, doubtless *S. arundinacea*. I gathered specimens of the Grass in both islands, and the inflorescence and

growth appeared to be identical. In the penguin rookeries this Grass, known to the inhabitants of Tristan as "Tussock," has a habit which appears to be closely similar to that of the Falkland Tussock, *Dactylis caespitosa*, as described by Dr. Hooker in the "Flora Antarctica," p. 384. The Grass grows to a height of 5 or 6 feet. It springs in tufts, and forms massive boles or clumps at its base, composed of the contorted bases of the stalks and root-fibres closely matted together. These masses are tough and hard, almost requiring an axe to cut them. The Grass thrives best where the ground is saturated with the penguin's dung. The basal masses gradually pass into a peaty condition; and in the rookeries there are beds of black peaty richly-manured soil, thus formed, several feet in thickness. The growth of the Grass is so dense that it is with the utmost labour that a way can be forced through it, except along the penguin roads; and it is so high, that it is only by mounting on an occasional rock, fallen from above, that the direction which has been taken can be made out.—*Linnean Society's Journal*.

ODE.

Dedicated to the Hon. Marshall P. Wilder, twenty-five years President of the American Pomological Society.

FROM him who was lord of the fruits and the flowers
That in Paradise grew, ere he lost its possession,—
Who breathed in the balm and reposed in the bowers
Of our garden ancestral, we claim our profession;

While fruits sweet and bright
Bless our taste and our sight,

As e'er gave our father, in Eden, delight,
And fountains as pure in their crystal, still gush
By the Vine in her verdure, the Rose in her blush.

While others into clouds sit to murmur and grieve
That Earth has her Wornwood, her pitfalls and Brambles,
We, smiling, go on, her rich gifts to receive,
Where the boughs drop their purple and gold on our rambles.

Untiring and free,
While we work like the bee,

We bear off a sweet from each plant, shrub, and tree,
Where some will find thorns but to torture the flesh,
We pluck the ripe clusters our souls to refresh.

Yet not for ourselves would we draw from the soil
The beauty that Heaven in its vitals has hidden;
For, thus to lock up the fair fruits of our toil
Were bliss half-possession and a sin all-forbidden.

Like morning's first ray,
When it spreads into day,
Our hearts must flow out, until self fades away.
Our joys in the bosoms around us, when sown,
Like seeds, will spring up and bloom out for our own,
And this makes the world but a garden, to us,

Where He, who has walled it, his glory is shedding,
His smile lays the tints; and, beholding it thus,

We gratefully feast while his bounty is spreading.
Our spirits grow bright
As they bathe in the light
That pours round the board where, in joy, we unite.
While the sparks that we take to enkindle our north,
Are the gems which sprinkle down o'er the earth.

And, now, that we meet, and the chain is of flowers,
Which binds us together, may sadness ne'er blight them,
Till those who must break from a compact like ours,
Ascend, and the ties of the blest re-unite them!

May each who is here
At the banquet appear,
Where Life fills the wine-cup, and Love makes it clear.
Then Gilead's balm in its freshness will flow,
O'er the wounds which the pruning knife gave us below.

MISS HANNAH F. GOULD.

OBITUARY.

DR. LANKESTER.

WE have to announce the death of Dr. Edwin Lankester, whose name has been somewhat intimately connected with the progress of botany and horticulture for many years. Dr. Lankester's first important work was the "Natural History of Plants Yielding Food," a book full of interesting research, carefully put together; and his "Memorials of John Ray" and the editing of the correspondence of the greatest of English naturalists were welcome contributions to the annals of natural history. He subsequently published an excellent translation of Schneider's "Principles of Scientific Botany;" and, by command of her Majesty, edited the "Natural History of Dee Side;" and, in 1868, appeared his "Vegetable Physiology." These and many works in other branches of science, and innumerable lectures given during his various professorships, completely filled a life of unceasing and ever-useful industry, which has been closed at the comparatively early age of sixty-one.

* Under this head we propose to give twelve calendars during twelve months, detailing the practice of one of the best market gardeners near Paris.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
The ART ITSELF IS NATURE."—*Shakespeare.*

PLANTING HILL-SIDE APPROACHES.

By JAMES M'NAB, Royal Botanic Gardens, Edinburgh.

FROM time immemorial, people have selected wooded mountain sides or elevated plateaus for building sites, from which extensive views of the surrounding country might be readily obtained. At the present time in the west of Scotland, on the elevated lands along the shores of our inland lochs (or arms of the sea as they are termed), every available spot has been taken advantage of for building purposes, and the same arrangement may be observed round the shores of most of the celebrated watering-places throughout the United Kingdom. A few hints, therefore, as to the laying out of certain portions of the grounds round such houses, particularly the approaches leading to them, and the flower-garden department, may not be altogether unacceptable to your readers. The making of a carriage road leading to some of these hill-side residences, is often fraught with considerable difficulty; sometimes a passage has to be cut out of solid rock, or rock covered with soil or clay, and often amongst thick forest vegetation. In some cases blasting to a considerable extent has to be resorted to, and the after beautifying of these crude slopes, which in no place ought to exceed 8 or 10 feet on the highest side, is often considered by the proprietor to be attended by many difficulties, which, in most cases, are only imaginary. In order to take off the wall-looking appearance which many of these cuttings are apt to present, the line of drive should be curved as much as possible, and the sides of these cuttings should be made somewhat shelving, with here and there portions more or less sloped backwards; if rocky, the steeper parts should be so arranged as to form as many spaces as possible for the purpose of holding soil, in which a variety of plants can be grown, or seeds sown, the kinds selected being such as naturally frequent similar localities, such as the Wild Wallflower, Snapdragon, Rock Catchfly (*Lychnis Viscaria*), Foxglove, Viper's Bugloss (*Echium vulgare*), Evening Primrose (*Oenothera biennis*), Columbine, and many other plants of a similar character; on the lower parts might be sown seeds of *Linaria alpina*, so abundant along the rocky passes in Switzerland, besides *Anthyllis Vulneraria*, *Geranium Robertianum*, *G. lucidum*, *Dianthus deltoides*, *Valeriana montana*, *Corydalis lutea*, and a host of others. Perennials, Alpine, herbaceous, and trailing shrubby plants, are also admirably adapted for such rocky cuttings, such as *Lysimachia nemorum*, and *L. nummularia*, *Convolvulus arvensis*, *Fragaria lucida*, *Polygonum vacciniifolium*, *Veronica alpestris*, various Primroses, all the trailing species of *Potentilla*, such as *P. repens* and *P. stolonifera*, *Periwinkles*, *Arctostaphylos Uva-ursi*, *Cotoneaster microphylla*, *Helianthemum*, *Eriogonum*, and many varieties of the small-leaved Ivies. Native Ferns should be very freely planted in such situations, and if the rock is at all of a soft character, it will render the insertion of roots the more easily accomplished. The tufts should be put in any time during the winter or spring months, at which period the plants are in a resting condition. The chief object to be kept in view, is to render these artificial rock slopes in keeping with the surrounding scenery. It is not to be expected that such places are to receive the same attention as a regular artificial rockery; on the contrary, they should be left a good deal to Nature. If portions are so constituted as to allow peat soil to be put in, many of the better kinds of Ferns could be introduced. In some places trees of large size have to be cut down along the upper surface of such slopes, and frequently great expense is incurred in rooting them up; such tree stumps, if partially opened by a slight blast of gunpowder, or by the dynamite process, become excellent receptacles for hardy Ferns; a little peat mixed with sand, or heavy loam, being previously put in to fill up the crevices. In such positions, the Royal and Ostrich Ferns present a noble appearance; also, the Crested Male Fern, surrounded by any of the ordinary British dwarf sorts, as the Oak, Beech, and Holly Ferns, Hart's-tongue,

and other Cryptogamic plants, such as *Lycopodiums*, *Equisetums*, and vegetation of a similar description. In some localities smooth and rocky surfaces interfere with the intended arrangements, but such places can also be made available for Ferns and other plants by being opened up with a blast of dynamite, filling the openings thus made afterwards with soil, and planting in the same manner as recommended in the case of old tree roots. Such situations cannot be kept altogether free from the natural Phanogamic plants of the district, but that matters little, as a clothed surface is what ought to be aimed at; besides, the beauties of the native vegetation become enhanced by having a better class of plants introduced amongst it. Here and there loose stones or portions of rock may be piled together in heaps with irregular outlines amongst the tree stumps; and, if the spaces between the stones be filled with the natural surface soil, they will be found to be excellent places for Ivy, *Cotoneasters*, and *Periwinkles*. Rude as such constructions are, they furnish variety, and use up to advantage material that might otherwise lie about in the shape of unsightly rubbish. For sloping rocky sides *Rhododendrons*, particularly the varieties of *R. catawbiense* and *R. ponticum*, are admirably suited; and if it can be arranged to introduce some peat soil they will thrive well and soon partially conceal large portions of the rock. The *Rhododendrons ferrugineum* and *hirsutum*, if planted on some of the lower ledges, will also soon form interesting objects. In such situations few plants will be found more pleasing than the *Azalea pontica*; its Honeysuckle-looking heads of yellow flowers are interesting during the summer months, and its glorious crimson leaf-tints during autumn make it a beautiful object for such rocky approaches, as well as in the open spaces of the more trimly-kept approaches in lowland districts. *Fuchsia Riccartoni* can be easily introduced into such situations, and will be found to grow and flower admirably; and, if the locality is at all exposed to the sun, young plants will be found to come up freely from seed on many of the projecting rocky cliffs. The *Deodar* is a very desirable tree for placing here and there along the top of the banks, provided there is depth enough of soil for it; the upright growth of its stem and pendent branches make it a peculiarly graceful object in such positions. An infinite variety of other plants, and contrivances for their reception, even in a rustic manner, are much more in character with the surrounding scenery, and more pleasing to the eye, than the attempts which are sometimes made to modernise such places, and fill them with plants quite unsuited to them. Round such hill-side or mountain residences we often see flower plots cut in regular geometrical figures, filled with scarlet *Geraniums*, *Verbenas*, *Calceolarias*, and similar plants, which do not in the smallest degree harmonise with their surroundings, particularly in places where wild mountain scenery, although distant, is seen from the flower garden. This gaudy foreground of crimson, blue, and yellow, and other strong colours which such flower plots generally exhibit, frequently outstrips the richly-tinted hills, even though their tops and sides glow with native Heath. Instead of gay flowers, such mountain residences ought to have clumps or compartments formed of rock-work, standing on Grass. Garden decorations of this kind look infinitely better, and are more in keeping with the surrounding scenery than the generality of those now to be seen. Useful stones for the formation of rock-work are generally abundant in such localities. Many of these artificial mounds may consist almost entirely of rock-work, the higher portions of which should be clothed with hardy Ferns of the taller and better kinds; and the sides, if not all composed of Ferns, may be filled with hardy perennials or summer flowering bedding plants, while other clumps may be cut out in the turf, or formed with rock-work sides, and filled with the better class of hardy Heaths, such as the double-flowering *Calluna vulgaris*, *C. Alportii*, *C. Serlii*, and *C. Hammondii*, *Erica cinerea* of different sorts, *E. mediterranea*, *E. vagans* of sorts, as well as the dwarf *Menziesias*, *Andromedas*, *Daboecias*, and similar plants. Such species, having flowers of partially subdued colours, are very suitable for hilly districts; besides, such plants are not liable to be injured by early frosts, a circumstance which too often happens in the case of ordinary bedding plants in high situations; the more tender plants, indeed, rarely arrive at

maturity in many high-lying districts, where they suffer much from late spring frosts, from which they have often scarcely recovered before they are overtaken by the early autumn colds. Under these circumstances the varieties of natural mountain plants are better adapted for such situations—either in or out of flower, provided they are well kept in shape—than any others. In no instance are plants in a state of nature to be seen in our mountain districts with gaudy-coloured flowers, although they frequently abound in corn-fields. In the case of lowland scenery, where the land is naturally level and little seen beyond the boundary of the flower garden, the system of massing gay colours together is less objectionable. Our mountain districts are now very much frequented by tourists from all quarters of the globe, and all seem delighted in seeing the green Moss-covered dry stone walls (or dykes as they are termed) literally clothed with common native Ferns. The same amount of pleasure will be experienced if the artificial rocky avenue slopes alluded to are made to resemble them. This style of approach has recently been carried out in a scientific manner on the steep avenue banks at Fetter Mount, Lasswade, near Edinburgh, where Mr. Potts has rendered the artificial slopes leading to his mansion most interesting, these being clothed with a series of native Ferns and perennial Alpine plants, particularly species of the genus *Saxifraga*, *Sedum*, *Sempervivum*, *Aubrietia*, *Primula*, dwarf *Veronicas*, and a host of others, some of them having an interesting appearance during every month in the year. At the same time it is, perhaps, more thickly clothed with Alpine rarities than I would recommend for many of the avenues or approaches in mountain districts to which the observations just given more particularly refer.

NOTES OF THE WEEK.

— THE handsomest evergreen flowering shrub we have seen for some time past is *Arbutus Croomi*, now in flower at Glasnevin. In growth the shrub is like the common *Arbutus*, but the flowers are much larger, and have a rosy-salmon stain, which makes them very attractive. The shrub reminds one of the fine plants of *Eukianthus* seen in large conservatories and botanic gardens in Italy. Dr. Moore considers it a hybrid.

— FEW climbing plants are so brilliant just now as *Tropæolum Lobbianum*, which is literally a mass of scarlet, rendering many a cottage porch, even thus late in the year, quite gay with flowers.

— MR. BRUSH, gardener to Lady Hume Campbell, showed at South Kensington on Wednesday last, a Neapolitan Violet, which is a decided improvement on the common Neapolitan kind, richer in hues and larger; it was introduced from the south of Spain, to Lady Hume Campbell's garden at Hlgh Grove. Mr. Brush also showed a very promising purple tree Carnation, named Lady Faller.

— ACCORDING to the *Kentish Observer*, a large kind of Sloe or Wild Plum, peculiar to the country around Halstead, and known locally as "Skeggs," growing in hedgerows and fruit plantations, has been very abundant this year. It is estimated that in the parish of Halstead alone 8,000 sieves will be gathered. It is the largest growth ever remembered in the neighbourhood, the fruits hanging in such dense clusters that the trees are obliged to be propped. A good hand can pick from ten to twelve sieves a day, and the price usually paid for gathering is about 6d. per sieve. The fruits are used for making what is known as British port wine.

— IN Sweden gardening forms a part of the educational system. Upwards of 2,000 schools have gardens for planting attached to them, and the teachers of elementary schools are obliged to learn gardening. There is a garden attached to the Higher Bungher School at Utrecht, in which botanical specimens are planted, arranged, and classified by the pupils. To some extent, gardens have been apportioned to schoolboys in this country, but rather as a means of recreation than of study. The Duke of Northumberland's School, at Alnwick, affords an instance in point. But it is worthy of much wider adoption in country districts.

— PROFESSOR GABBA has been examining the effects of ammonia on the colour of flowers. It is well known that the smoke of tobacco will, when applied in sufficient quantity, change the tint of flowers; but Professor Gabba's experiments consist in pouring a little ammonia liquor into a saucer and inverting a funnel over it. Placing the flowers in the tube of the latter, he finds that blue, violet, and purple-coloured blossoms become of a fine green; carmine and crimson become black; white, yellow; while parti-coloured flowers, such as red and white, are changed to green and yellow. If the

flowers are immersed in water, the natural colour will return in a few hours. Professor Gabba also found that Asters acquire a pleasing odour when submitted to the fumes of ammonia.

— *BROWNEA COCCINEA* is now blooming in the Aroid-house at Kew, and is very ornamental, its pendent clusters of flowers being of a rich scarlet colour. The large white-flowered *Dahlia Imperialis* is also flowering freely in the Palm-house.

— TO the usual attractions at the Crystal Palace there is at present added a fine display of Chrysanthemums, which are well worth a visit. They will be found effectively arranged in the centre transept.

— THOSE interested in Orange culture may like to know that a series of letters written by J. H. Fowler, of Port Orange, and printed in the *Florida Agriculturist*, has been published by C. H. Walton & Co., of New York, in a pamphlet form. It is a subject on which small practical books are scarce.

— A FRUIT-GROWING correspondent writes to us to point out how admirably the ingenious ice-house arrangements shown in the *American Agriculturist*, and reproduced in last week's GARDEN, are calculated for the long and perfect preservation of choice fruits and vegetables.

— MR. WILLIAMS's new Maiden-hair Fern (*Adiantum gracillimum*) has now been proved to be the most remarkable of all recent introductions in its way; the plant shown at Kensington on Wednesday last, was a marvel of graceful beauty. It is destined to become as popular as the old *Adiantum cucuatum*.

— SOME very fine specimens of the white Calville Apple, grown in Mr. Leigh's garden at Barham Court, Kent, were shown at Kensington on Wednesday last. It will be remembered that it was at one time supposed that this Apple could not be grown in perfection in the open air in this country.

— A RECENT gale demolished a stately Thorn tree, considered the largest, if not also the oldest, in Scotland, which, for many generations, has stood in close proximity to the old Greigston Mansion House, Cupar, much admired in summer when mantled in white blossom, and in winter for its old weather-beaten aspect.

— THE widow of the late Joseph Locke, the eminent engineer, presented a park of some 18 acres to the town of Barnsley, and invested £3,000 in Consols to maintain it. Miss McCreery, the only surviving sister of Mrs. Locke, has just presented three parcels of ground, which will make the park 40 acres in extent.

— ONE of the largest importations of *Todeas* ever made to Europe has (says the *Scotsman*) just been received at the Bangholm Nurseries of the Lawson Seed and Nursery Company, and admirers of such Ferns would do well to pay them a visit before they are distributed. The collection numbers about 500 specimen plants, and it is contained in two large houses.

— A MOVEMENT is in progress for securing the laying out of a new park or recreation-ground on a plot of land adjoining the Metropolitan Extension line of the London, Chatham, and Dover Railway, situated between the Loughborough Junction and Camberwell New Road Stations. The ground in question, which is about 13 acres in extent, is known as Myatt's Fields, and was, until within the last two or three years, occupied as market gardens.

— THE Lindley Medal has at last been prepared. It is a handsome work of art, and its value is estimated at £15. On the obverse side is a portrait of Dr. Lindley, enamelled with a Laurel wreath, and the inscription, "Dr. John Lindley, F.R.S., born February 5th, 1799. Died November 1st, 1865;" on the reverse, Flora with a wreath in her left hand, and the inscription, "Royal Horticultural Society."

— A PAPER has lately been read at the Paris Academy of Science, on the fermentation of Apples and Pears, by MM. G. Lechartier and F. Bellamy. The experiments described have been carried on since 1872, and are considered by the authors as a demonstration of Pasteur's deduction from his theory of fermentation, that "the formation of alcohol is due to the fact that the chemical and physical life of the fruit cells is continued under new conditions in a similar manner to those of the cells of the ferment."

— LONDON, one of the healthiest cities in the world, might be much more so by the general adoption of a movement now going on in Camberwell, to provide a public park and children's playground for that locality. The ground, once occupied by market gardens seems admirably fitted for the purpose, and might, at a little cost, be appropriately laid out. The demoralising life led by the children in the streets more than justifies the promoters in their house-to-house canvass in favour of the scheme. We, *Lancet*, hail the movement as one likely to be followed up in other neighbourhoods where John Knox's saying *apropos* of the monasteries and their inmates, "Ding down the nests and the rooks will flee away," might be parodied with even more salutary effect, "Ding down the rookeries and disease will flee away."

THE INDOOR GARDEN.

COCHLIOSTEMA JACOBIANUM.

This singular plant, with Agave-like foliage, and somewhat Orchid-like blossoms, is one of great beauty. A plant belonging to the same genus was introduced to our gardens some few years ago, and more than one of our principal nurserymen flowered it successfully. M. E. André, however, who, in the *Revue Horticole*, recently gave a figure of what he deems to be a new species, appears to think that the elder species is now entirely lost to our English gardens; but, whether he has sufficient proof that such is the case we doubt, as the name appears in some of our nurserymen's catalogues. He speaks pretty confidently, however, of its disappearance from the establishment of Messrs. Veitch, and also from that of M. Verschaffelt, of Ghent. Our engraving will serve to convey an excellent idea of the Agave-like foliage of the plant described as a new species by M. E. André. A wood engraving, however, can give no idea of the beauty of its inflorescence. The petals of the flowers, which are of a soft velvety purple, measure $1\frac{1}{2}$ inches across, while the sepals are of a pale rosy-white. The spoon-shaped bracts are of a deep

Cochliostema Jacobianum.

bright salmon colour, the whole of the stalks being of a paler tone of the same colour, flushed at the joints with a full-brownish pink. The flowers exhale a delicate perfume, similar to that of certain *Oncidiums*, to the blossoms of which they present a superficial resemblance. The beautiful flowers of *C. Jacobianum* have the defect of being exceedingly evanescent, as noticed in the previously-known species which has flowered in England. This defect, however (which is peculiar to nearly all *Commelynaceae* plants), is more than counterbalanced by the profusion with which the flower-spikes are seemingly produced on well-grown plants. In the new (?) species described by M. E. André, he relies for its distinctness on the following differences from the old one. First, by the far less hirsute character of the flowers; and, secondly, by the uniform green of the leaves, the elder species having them either strongly blotched or bordered with purple. He also relies on the much larger general dimensions of the plant. It is presumed that so large a plant can only be an epiphyte upon some of the forest giants that clothe the deep slopes and valleys of equatorial America. In a shaded part of the stove it is not difficult to flower, and its multiplication may be effected by the separation of the small lateral biddings until seeds shall have been obtained. It is well worthy of a place in the Orchid-house. N.

WINTER TREATMENT OF HALF HARDY PLANTS.

Will you kindly tell me how I may preserve several scores of scarlet, Mrs. Pollock, and Bijou *Geraniums*, scarlet, white, and purple *Verbenas*, and *Calceolarias*; and, also, how to make the best use of two frames which I have just built—each being 12 feet long, 4 feet wide, 3 feet high at back, and 2 feet at front. The walls are 4-inch brick, Portland cemented outside. Should they be plastered and whitewashed inside? The floors are of thick flags on a dry rubble bottom, with a grate, gulley, and drain to each frame to carry off the water after watering. A 2-inch pipe runs round each, and is heated by a boiler in my house cellar; by a valve between the two frames the hot water can be confined to one, and the other left cold. I have about 450 plants, and each frame will hold about 300. To begin with, the plants have just been taken out of the beds and potted just as they are, singly in 18-sized pots, and placed on tiers of deal boards close to the glass. As this climate is very wet the *Geraniums* grew like Cabbages in my rich beds and hardly flowered at all, so I want to try keeping the old plants and plunging them in their pots in the beds next summer. Can *Verbenas* and *Calceolarias* be so treated? As I intend buying fresh bulbs every year so as to be able, by turning them out of the borders as soon as they are past their prime,

to gain a lot of space for succession crops of flowers, I shall have to propagate and preserve a number and variety of plants; and, on account of the proximity to the house, I do not wish to put manure in the frames for a hot-bed. Can I manage to get three successions, say (1) bulbs, (2) brief summer-flowering plants—or what? (3) *Gladioli*, *Tritomas*, &c., brought on in the frames and put in beds in their pots. Can I make any use in winter of a warmly-built but unheated summer house, 8 feet square, which can be either made very light or darkened. I shall be greatly obliged if you will kindly instruct me how to treat my bedding plants and make the best possible use of my frames. LANCASTRIAN.

[Reply by Mr. Baines.—Whitewash the inside of the pits, on the bare bricks, which should not be plastered. Your *Geraniums* should be wintered in the pit nearest the boiler, which, as a rule, may be kept a little warmer in cold weather than the other, where the *Calceolarias* and *Verbenas* are, neither of which are of much use, except to take cuttings from towards the end of February, when they may be struck, either in a dung frame or in the pit nearest the boiler, which should then be kept continually warm for the purpose, the *Geraniums* being transferred to the other pit. In future, the *Verbenas* should be struck in a close cold frame in August, and the *Calceolaria* cuttings in the middle of October, also in a similar situa-

tion, just keeping the frost from them during the winter. The Geraniums will do better planted out next summer than plunged in the pots; peg the shoots down at planting time over the surface of the beds; they will then be less disposed to make too much growth. Propagate Lobelias, Heliotropes, Fuchsias, and Ageratums at the end of February for bedding out. Remove the bulbs from the beds just before the time has arrived for turning the bedding plants out; these latter will keep on blooming until frost cuts them off, consequently you will not require a third lot of flowering plants. The Gladioli, Tritomas, and similar plants will do much better by themselves. After the plants are turned out of the pits in spring, Cucumbers or Melons, or both, might be grown through the summer in the pits; or, if flowers were more in request, a few Fuchsias or pot varieties of Zonal Geraniums, with autumn-flowering Lilies. The different varieties of *L. lancifolium* will be the most useful, but, in a limited space, such as the pits afford, avoid over-crowding or attempting too much. The summer-house, unheated, will not be of much use in plant-culture in winter.]

IMPROVED CULTURE OF THE LILY OF THE VALLEY.

THE chief varieties of this charming plant are the common *Convallaria majalis*, *C. majalis flore pleno*, *C. majalis rubra*, and *C. majalis variegata*, the last a variety with golden striped leaves. Sweet, chaste, and beautiful as the Lily of the Valley was, and is, it remained in comparative obscurity till within the last few years. The roseate variety is neither common nor much liked, as the whiteness of the Lily of the Valley is one of the greatest of its charms. A coloured Lily of the Valley would hardly be deemed to smell as sweet; neither is the double variety any improvement, but the reverse; it gives a sort of stiffness to the flowers that robs them of their elegance. The golden leaves are not very constant, and if they were, could hardly compensate for the loss of the peculiar and charming green of the normal leaves. The mode by which the Lily of the Valley rose from comparative neglect to universal popularity is peculiar, and worth noting. It somehow entered into the mind of an enterprising person in the country that it would prove at once a pleasant and profitable speculation to carry some of it into the towns. No sooner thought than done. Numbers were collected, fringed with foliage, and dispatched to London and other centres of population; baskets and bunches were hawked along the streets, and the cry of fresh Lilies of the Valley from Woolpit, and other woods, became common in Shoreditch and the Strand. The sweet flowers quickly found their way into wealthy mansions, and in this, and other ways, such an insatiable demand was created for this charming flower as hardly all the modern resources of horticulture can suffice to meet. Fortunes are being built up on this humble plant; it employs thousands for several months in the year, in this and other countries; it is the most favoured of all the plants that come into Covent Garden Market, in the winter and spring months, and loaded with little green-tipped lamps of white, is, undeniably, a queen among flowers. As in many other cases, the demand has not only created a supply, but improved its quality, and extended its season. At one time, Lily of the Valley in plenty in May and June sufficed; now it is wanted from December to August. At first, too, any flowers and foliage were good enough, the perfume and the freshness of leaf and flower satisfied; now, flowers and leaves alike have to be developed to the uttermost, to satisfy the growing demand for quality in both.

The resources of the plant, and the skill of the cultivator, have both been taxed to meet the new requirements. It will not do now to go to the native haunts of this sweet Lily, and dig up a barrow load of roots for forcing, as of old—neither is it enough that an old shady border in some out of the way place is devoted to its cultivation. The best modern modes of cultivating this plant is well told by Mr. F. Sander, seedsman of St. Albans, from whom we quote. To have it in perfection, it must have a bit of the richest soil England can furnish, and be liberally nurtured with water during dry weather. Continental growers seem to have first discerned how amenable the plant was to high cultivation. They set about growing it as they did Hyacinths and Tulips. By incessant sub-division, and annual or biennial planting in rich soil, they grew plants so fine, and strong as to be thought a superior, and quite different variety. It is, however, only the difference between a liberal and starving system of cultivation. It was this superior mode of treating the Lily of the Valley, and the continued demand, that originated the clump system. The crowns grew so strongly, and produced a series of other strong crowns around them, forming the large clumps that were transferred to the English and foreign markets just as they grew. The trade purchased, and growers gladly bought, and still buy these clumps; they are an immense improvement on the old plan of taking up patches of any and every sort from

wood, and border for forcing. It is, however, obvious that the clumps must contain a mixture of flowering crowns and leaf crowns, and so far there is a loss of space in forcing such; besides, the carriage of clumps is heavy, consequently expensive; but the system is not a bad one, especially for those who grow their own clumps. The single crown system is better, and will speedily supersede it. It is more certain, requires less space, and is therefore more economical; only the strongest flowering crowns are picked out, and each of them holds a flower in embryo, as shown in the annexed engraving.

The mode of cultivation, on the single crown system, also tends to develop the full strength of each crown. Plants are picked over annually or biennially; all the finest crowns being selected, and the others planted on fresh ground. By such means the entire energy and skill of the cultivator is directed to the development of individual excellence; the consequence is, that the crowns improve from year to year, and seem in a fair way of overtaking ordinary Asparagus heads. Space in heat is always costly in winter and early spring, and as a dozen or more single crowns may be flowered to perfection in a 4 or 5-inch pot, both space and heat are economised. These pots, fully furnished and in flower, are a sight to gladden the eyes, and cheer the hearts, of all lovers of beauty. The flowers stand up boldly above the foliage; and the Lily of the Valley, by the single crown system, has assuredly risen in the world. They should be potted rather firmly in rich soil, and placed in a gentle heat; it is better to keep them in a shady place until fairly started, when they may be gradually inured to the light. Some keep the plants in semi-darkness until the flowers are almost expanded; in that case there will be few or no leaves. For cut flowers that may not matter, but for plants in pots, the furnishing of vases, &c., the leaves are as essential as the flowers, and must either be developed by growing the plants in the light, or forcing clumps of common plants in boxes, specially for foliage; it may be well in private establishments to do this, if the crown system is adopted, lest a scarcity of foliage should occur. Some ladies like to see a thicket of leaves, studded over with the charming crystal flowers. It is well, too, with crowns, to excite root action rather in advance of the top, as it will be apparent to those familiar with the crowns and roots of the Lily of the Valley, that there cannot be a very large portion of root to each; but the root is the part always on the move for extension and reproduction, and, with a little genial treatment at starting, it will be sufficiently developed to sustain the flower-stem through its flowering period. More need hardly be added on either the crown or clump system; the former is now firmly established. Nearly all the beautiful plants that are sent to Covent Garden Market are the produce of single crowns. The system is founded on a true principle; the more all such plants as these are sub-divided the stronger the separate parts become. Multiplication of parts, if skilfully managed, leads to a concentration and augmentation of vital force. This is exactly what is wanted in such plants as Lily of the Valley, *Hoteia japonica*, Violets, *Myosotis*, and others used for forcing and furnishing. As to the exact mode of procedure, the plants should not be kept too long out of the ground; lay in the crowns, as soon as received, behind a north wall. They must not be tempted to start out of doors. Put the first batch into the house in November, and succeeding batches every fortnight, and continue according to the demand till March. Place them in a close warm atmosphere, with little or no light and abundance of moisture. The crowns will push up with a rush, and soon break into blossom in a temperature of 65° to 75°. Very early and late blooms are somewhat difficult to obtain. Crowns will require sharper forcing to start in November than in January, and may be assisted with warm water early in the season, and a temperature from 75° to 80°.

To have Lily of the Valley in July and August, various retarding expedients must be resorted to. Among the most dangerous is to keep the crowns in a cold cellar, without earth, as long as possible; another method is, to pot them up, and place them in an ice well, or some very cold place, until their natural time of flowering is over; but very early, or abnormally late flowers, are hardly worth the trouble, unless for special uses, such as bridal bouquets, &c. The crown system with ordinary care, and a little more skill than is needed to grow them in patches and clumps, will yield a capital supply of Lily of the Valley, from December till March. About the end of May, and through June, the Lily of the Valley flowers in the open air, and by choosing two or more situations, one of the coldest, and the other the hottest, the garden can command, the season out of doors may be very much extended. Another point remains to be noticed, the crown system indoors will compel its adoption in the open air. It will hardly do to reverse the usual order of things in the case of the Lily of the Valley, and have much finer forced flowers than those that come in in their natural season. The starving system with which the plant has been treated in the open air will no longer be tolerated; it must have liberal treatment, and well-grown clumps or crowns be bought in, or prepared at home, for the production of

fine strong flowers, either for cutting, or for the forming of beds, clumps, edgings, &c. For all these purposes, prepared crowns would create a new sensation, and give a fresh pleasure. In fact, there is hardly a limit to the useful purposes for which prepared crowns or clumps might be used. The tendency of the plant, if let alone, is to exhaust the soil and itself, by multiplication of parts. We must take advantage of this tendency, and turn it to productive account by sub-division, and liberal culture in bed and border, pleasure grounds, and home plantations. Flowering the old crowns oftener than once in pots, as recommended by some writers, seldom answers well, and, if adopted, of course develops into the clump system; and a mixture of very small and a few large crowns is created. It may answer fairly with some of the later batches, but all the earlier lots are exhausted, and will not pay for again growing in pots; hardly for planting in the open air. Some of the later plants may be kept and flowered again; they will yield a fair supply of flowers and plenty of leaves; but, to do even so much, the plant must not be neglected after flowering, but carefully nurtured and tended, until the leaves ripen and die down of themselves, and not be allowed to wither from neglect. Better plant them out, and buy fresh crowns for the early batches for forcing; for, with all the care, time, and labour, bestowed upon old crowns, with the consequent expense, which will probably exceed, by many times, the cost of

Flowering crown.

Leafy crown.

maiden crowns from the trade, they will seldom or never approach these, either in size or profusion of bloom. Therefore, force fresh crowns, and fill the borders, pleasure grounds, and woods, with the old ones.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Epidendrum piliferum.—This singular caulescent species bears dense terminal branched spikes of flowers, the sepals and petals of which are of a bright apple-green colour, the lip being white with singular purple markings. Although not showy from a florist's point of view, this species is sure to find many admirers.—B.

Oncidium euxanthinum.—This fine golden-lipped species is now flowering in Messrs. Veitch's Nursery at Chelsea. It looks intermediate between *O. bifolium* and the far finer *O. varicosum* Rogersii; the purple-spotted and fluted pseudo-bulbs resemble the former plant, while the larger flowers and more stately inflorescence remind one of the last named. It is a winter-blooming plant of rare excellence.—B.

Pittosporums.—Permit me to inform your correspondent "Clara" (see p. 430) that the following varieties of *Pittosporum* are all distinct and well worth cultivating, and will grow well in any ordinary good soil:—(1) *Pittosporum Tobira argenteo variegatum*; (2) *P. coriaceum*, a kind with beautiful thick leathery foliage of a deep dark green; (3) *P. undulatum*, foliage glaucous and waxy; (4) *P. euzenioides*, leaves light green and pointed; (5) *P. Mayi*, a sort with pretty silvery under-foliage; (6) *P. crassifolium*, valuable for its blossoms, which somewhat resemble those of the *Escallonia macrantha*; this kind is somewhat more delicate than the other varieties, and also scarce and difficult to procure, except from botanical collections.—E. G.

Vellozia cœrulescens.—This is now coming into bloom in my hot-house. It is an exceedingly rare plant from Brazil, and it is also said to be common in the neighbourhood of Rio Janeiro. Its foliage resembles that of a small *Pandanus* with thorny edges, and the flowers are produced singly on the top of a slender stem, and somewhat resemble in shape those of one of the *Zephyranthes*, but have a more cupped throat. The white-flowered variety of this plant, *V. candida*, flowered for the first time about six years ago, at Glasnevin, where it had been raised by Dr. Moore from seeds sent to him direct from Brazil. It also seeded freely with him, and at one time he had a considerable number of young plants which he distributed to anyone who wished to possess them; but he recently informed me that he believed no one to whom he had sent them had been able to do anything with them, or even to keep them alive, and that he believed his own old plant to be again almost, if not quite, unique. He was anxiously hoping that it would soon flower and seed with him again. This curious and beautiful plant is well figured in the 91st volume of the *Botanical Magazine*. I shall be glad to hear from any of your correspondents if they have ever seen or heard of the *V. cœrulescens*, which may not now be so rare as when the plate of the white variety, above referred to, appeared.—W. E. GUMBLETON, *Belgrove, Queestown, County Cork*.

THE FLOWER GARDEN.

SHRUBBY CALCEOLARIAS.

ONE of the earliest and most effective of shrubby *Calceolarias* is that known as *aurea floribunda*, than which, as a yellow bedding plant, taking all properties into account—profusion and continuous flowering disposition, and its sturdy dwarf habit—nothing that previously existed or likely to follow will ever equal. There have been, as is well known to all who are conversant with garden matters, a number of other yellow *Calceolarias* raised from seed, as well as several of different colours, such as the orange Crown Prince of Orange, and their cultivation went on for some years, and without much difficulty, except in the driest parts of the kingdom in more than ordinarily hot seasons; but after a time they began to show symptoms of weakness by here and there a plant going off suddenly at the collar, until this defect became so aggravated as to assume the character of a disease, as virulent as the Potato blight, or that which now threatens to destroy the Tomato, both out of doors and under glass. This affection of *Calceolarias* was, from the first, most apparent in dry localities, where also the sub-soil was more than ordinarily porous, and naturally less able to retain any moisture after the surface soil became exhausted; but, as years went on, the disease, if such it is, became, in these dry situations, so bad, that virtually *Calceolarias* as bedding plants could not be grown. I noticed from the first that the more popular the variety, and, consequently, the further its propagation was pushed, the more it was affected. At that time, I was living in Cheshire, and the flower garden was, like the rest of the place, in an extremely dry situation, having a deep sandy sub-soil. Here, despite thorough and continuous watering, the *Calceolarias* became difficult to manage. A reserve stock was kept in readiness to take the place of such as died off through the season; but ultimately the plants died off in such numbers as to compel my relinquishing their cultivation altogether as bedding plants, under the ordinary system of propagation. When we see a plant that has at one time conformed to a particular system of culture, and then, without any alteration in its general treatment or other external conditions as to its existence, refuse to grow, it is advisable to ask ourselves a few questions—or, in other words, look for the causes, which either must be traceable to the advent of some malady hitherto non-existent, or the treatment the plant has received at our hands having been such as gradually to weaken its constitution, and render it a prey to disease. Impressed with this general conviction, I approached the subject, first considering the nature of the plant. These bedding *Calceolarias* have directly descended from evergreen shrubs, that even under cultivation will assume the dimensions and get as hard in their wood as a Gooseberry bush; they are also, from their natural habitat (Chili), necessarily moisture-loving plants. In thinking over these natural conditions of the shrubby *Calceolarias*, it occurred to me that, in the numbers of plants which we cultivate for different purposes, few are subject to treatment so opposed to the natural conditions under which they exist as these. Used as they have been for bedding, their general treatment, especially the condition of the plants from which the cuttings are taken year after year, is different in every way from plants which in their natural state would be sufficiently mature to take cuttings from; and, therefore, plants that in themselves have never attained a condition comparatively beyond a mere sappy shoot—or in other words, never have had time to attain their natural mature hard-wood state—are not in a fit state to furnish cuttings. This view was still further confirmed by noticing the difference that existed between the plants grown in pots during the first year after being struck, and such as had been so kept until they had time to develop and solidify their parts by age. As is well known by those who grow the most useful decorative yellow variety, *aurea floribunda*, that, if ever it gets neglected for water during the first season, especially in the spring whilst it is young, it is very liable to die off suddenly through the effects; yet the same variety, if it lived over the first year so as to get its main stem and the base of the branches solidified to something like their natural condition, would stand a great deal more rough treatment, even if it suffered so much for want of water as to cause its leaves to flag. I happened to have some plants that had been used for conservatory decoration for five or six years, being yearly pruned back like a *Pelargonium* (but not so closely), and a portion of the soil removed, and then re-potted; the plants never occupied pots above 12 inches in diameter, yet they used to flower profusely most of the summer. It struck me that cuttings taken from plants in the above condition might probably be stronger in constitution than such as were, each succeeding year, taken from plants that themselves had not had a separate existence long enough to get any portion of their wood matured in a way natural to the plant—in other words, a continuous reproduction from cuttings that were the produce of soft growth. With this view I struck a number of plants from the soft points of

these hard woody plants, and found them, although not altogether disease-proof, yet far less subject to it, either in the flower garden, or their early existence as pot plants. All this, of course, does away with the variety as a bedder; for, where largely grown, it would be out of the question to procure sufficient cuttings in this way. The experiment simply goes to prove that cuttings taken from plants old enough to have their wood fully developed and matured will, in the case of this *Calceolaria*, make stronger plants, better able to withstand treatment somewhat contrary to their natural requirements; the first of which undoubtedly is a plentiful supply of water, especially in their younger state, of which a knowledge of the *Calceolaria*'s native habitat is sufficient to convince anyone who has studied the laws which govern vegetable life in respect to the requirements of water. Cultivation through successive generation of most plants will go far to alter their general appearance—even so far as to make their origin scarcely recognisable. Yet there is one essential which they never lose—that is, their requirements in the quantity of water, especially at the root, and to a less degree in the atmosphere. Of this we may see proofs innumerable around us on all sides. Independent of its use for bedding purposes in such localities as it will succeed in without an unreasonable amount of attention, *aurea floribunda* is a first-rate plant for general decoration, grown in large or small pots for conservatories and similar places. The great use of subjects of this description, especially grown in, say, 6-inch pots, is that they can be stood about where there would be a hesitation in placing things of greater individual value. If well attended to, the plant will keep on flowering all the summer, but in this young state it must never be allowed to suffer for want of water. It is largely grown for Covent Garden Market; its numbers being only limited by the cuttings available. They are treated in the ordinary way—struck in cold frames, and in such kept through the winter quite cool, but well protected from frost, with litter and mats. The plants are encouraged to grow, and removed to 6-inch pots early in the spring, then pushed along by keeping moderately close, so as to get them early into flower, stout, and bushy. One thing that makes them sought after is, they supply a colour not over-plentiful in pot plants. T. BAINES.

COLOURS OF FLOWERS.

As, in "Notes of the Week" (see p. 422), you quote a letter from *Nature* on this subject, without intimating that it contains merely the opinion of a correspondent, you will, perhaps, kindly allow me to call attention to the very similar replies to that letter, by myself and Mr. T. Comber respectively, in the subsequent number of that journal. I venture to repeat the arguments contained in them:—1. The greater size and brilliancy attained by cultivated flowers is due, in most cases, to intentional artificial selection by the cultivator intensifying slight variations. Where cultivation affects the first cultivated individual, Mr. Darwin thinks the variation may originate, as suggested by Knight, in the change or excess of food ("Origin of Species," chap. i.). 2. Double flowers, as pointed out by Mr. Thomas Meehan, are of various origin, some only arising from metamorphosis of stamens or pistils, and being consequently more or less barren; others are due to the development of normally suppressed intercalary whorls, or possibly to chorisis. Either excess or lack of food predisposes to disease; so that the abortion of organs fitted for the exhausting reproductive process may, perhaps, be caused by weakness, or by an excessive growth of parenchyma arising from over-nutrition. Double flowers are not permanent in a state of nature; though they might be so, as, Mr. Darwin mentions ("Origin of Species," chap. viii.), varieties of the annual Stock, which produce both double, sterile, and single fertile seedlings, fairly comparable with the fertile and neuter forms of social insects. Artificial selection is the main cause of double flowers. 3. The abortive flowers of the Guelder Rose and Hydrangea, as they grow naturally, are confined to the outer part of the corymbs, and serve the same purpose as the ray of Composite (which in some species, *Centauria Cyanus* for instance, consists of neuter florets) and the highly-coloured bracts of some plants, viz., to attract insects to the fertile flowers they surround. The large corollas originate, as shown by Dr. Ogle (*Popular Science Review*, April, 1870), according to the law of balancement of growth. Garden forms wholly sterile are the result of art. 4. The beauty of fruits, as shown by Prof. Hildebrand and Mr. Darwin ("Origin of Species," chap. vi.), "serves merely as a guide to birds and beasts, in order that the fruit may be devoured and the seeds disseminated." 5. "We meet very commonly with gaily-coloured chemical products, essentially connected with the normal processes of development (the chlorophyll of most non-parasitic plants, the rose pigments of Florideae, the many-coloured Lichens and Fungi), or decomposition (the tints of autumn leaves), and originating from venomous infection by insects (red galls). These colours appear to be merely an accidental quality

of the chemical products . . . natural selection is without any influence as to colours, unless animals are attracted or repelled by them." (Hermann Muller, *Nature*, vol. ix., p. 460).

G. S. BOULGER.

Singular properties of the Autumnal Crocus (*Colchicum autumnale*).—The strong resemblance of the *Colchicum autumnale* to the *Crocus* family, though it does not belong to it generically, will cause that popular name to cling to it, in preference to that of *Colchicum*. This plant has been recently found to possess curious properties which our readers will be interested to hear of, and to experiment on. The flowers, without absolute contact, are found to communicate a bright saffron-yellow to the fingers when held over the flowers, at a certain distance, and the colour so imparted remains permanently established for a considerable time, in spite of washing. The entire face, held over the flowers at a certain period of their development, assumes a jaundiced yellow of very pronounced character, upon which soap and water have no effect, but it generally disappears after a few hours, though, in some instances it lasts much longer. The near proximity to these flowers affects also the palate—a slight but astringent bitter taste being very perceptible. Some constitutions are so sensitive to the influences given off by this plant that the ends of the fingers become perfectly numbed by actual contact with the flowers. But these influences rapidly disappear when the inflorescence has passed its zenith. As is well known, the flowers appear in August and September, without leaves, the foliage having developed itself in spring, and died down before the appearance of the flowers. The spring leaves also appear to possess very strong properties, as well as the autumnal flowers; and, in the *Pharmaceutical Journal* of this month there is a short article describing the injurious effects of this Grass-like foliage on cattle, who nevertheless eat it greedily when the early spring Grass is late and poor. Some, it is stated, have died of the effects of this hitherto unsuspected poison.—WESTBOURNE.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Ivy on Cemented Walls.—If your Cumberland correspondent has cemented or rough-casted his house, and still wishes it covered with Ivy, let him put a light frame of wooden laths, crossed diagonally in the form of lattice work, round it. He can, in that case, keep the Ivy off the wall, which under some circumstances is desirable.—J. MATTHEWS, *Ivy Cottage, Weston-super-Mare*.

Artificial Rock-work at Otlands Park.—You will much oblige me by correcting an error in "H. N. B.'s" description (see p. 43) of my artificial rocks. They were not built by Mr. Marshall, of Liverpool, but by Mr. John Hancock, of Newcastle-on-Tyne.—W. C. HEWITSON.

Spring Flowers in Autumn.—The mildness of the weather has produced a spring-like aspect in many parts of the country. At Cudham, Primroses are in full bloom, the banks are covered with Violets, and the wild Briars are blossoming, which is most unusual in the month of November. The Holly trees are laden with berries this season.

Tree Carnations.—Some of the new kinds of Tree Carnations, as they are somewhat incorrectly called, are very beautiful. The varieties named *Gourdaunt*, *Comtesse de Strum*, *Pure d'Or*, *Oriflamme*, and *Mont d'Or*, all praised by that successful Carnation grower, M. Alegatiere, should be in every collection of such plants.—H.

Viper's Bugloss.—Another weed is recommended as a fine garden flower by a correspondent of the *Revue Horticole* (Dr. E. Solmi), who describes, in a very interesting letter to the editor, how much he had been struck in travelling between Paris and Corbeil by a titful glimpse, in a suburban garden, of a mass of beautiful deep blue flowers shot with rose-colour. An old gentleman opposite to him, perceiving his admiration, said, "Yes, they are very beautiful. I have admired them in their season for more than fifty years." "Yes, yes, I can well understand that, Sir," said Dr. Solmi, "but can you tell me the name of the plant?" "I can do that, too," said the old man, "for I am a little bit of a botanist; it is a lovely weed—*Echium vulgare*."

An Autumn and Winter Bed.—I have just seen a bed of foliage and flowering plants, which will last in good condition nearly all the winter, provided the weather is mild. The bed is circular in shape, and margined with a belt of *Cerastium Bibersteinii* fully a foot in width. Inside this is a broad row or rather double row of *Viola Imperial Blue*, then a row of *Bambusa Fortunei variegata*, followed by a broad band of purple-leaved Beet, the centre being a small *Yucca gloriosa* set on a carpet of Golden Feather. This bed is fully equal to anything I have seen this summer, and, being in a sheltered cosy sunny little nook, there is little danger of its beauty being entirely destroyed for some time to come.—B.

Standard Heliotropes.—I am prompted by the article on *Heliotropes* (see p. 339) to ask why they are not cultivated as standards. I never saw them grown in this way except by myself. I have them on 3 and 4 feet stems, with nice heads. By shaking off the old soil in spring, and re-potting in fresh loam and rotten manure, at the same time closely pruning the heads, they make fine plants in a few weeks, and continue to bloom for several months if occasionally treated with liquid manure. Probably there are but few of the varieties suited for this purpose, the chief aim of the hybridiser being dwarfness; none are the old *Heliotropum peruvianum*. I know of few things more grateful to the sense of smell than a walk between a double row of standard *Heliotropes* about one's own height in full bloom. We thus enjoy the delicious fragrance without either stooping or gathering the flowers.—J. M., *Hawkechurch, near Amersham, Devon*.

GARDEN STRUCTURES.

NOVEL MODE OF ARRANGING SUCCULENTS.

MR. PEACOCK'S Agave-house is a span-roofed structure, 40 feet in length and 20 feet in width, and contains a central shelf 10 feet in width and a side shelf 2 feet in width. On the sides are three tiers of brackets made of gas pipe in such a way that the pot is held in position by its rim, and so arranged that the drip from each plant misses the one below it. The brackets can be pushed backwards or forwards at pleasure by means of a screw, or, if not required, removed altogether; above these are shelves. This house contains about 500 specimen Agaves, and on the shelves are quantities of newly-imported ones, some of which promise to be new. Next come two half-span houses, one of which is filled with mixed foliage and flowering stove plants and a collection of Bromeliaceous plants, one end and the back wall being covered with Hoyas, and the other, or lightest, end with plants of *Nepenthes gracilis* major, now literally covered with pitchers. A house opposite this one is filled with Camellias. Next come two span-roofed houses, one of which contains a fine collection of the choicest sorts of Cacti, among which are some unique plants of their respective kinds. The Aloe-house is entirely devoted to Aloes, Gasterias, and Haworthias, of all of which there are very complete collections. Of a similar pair of houses, one is devoted to Euphorbias, Crassulas, Sempervivums, and Echeverias, conspicuous among which is the fine kind called *E. Peacockii*. This house also contains a collection of Yuccas, some of which are unique in their way, likewise *Dasyliiums*, and on the shelf some fine *Stapelias*, the opposite house being devoted to miscellaneous greenhouse plants. In addition to these is a pair of low span-roofed Orchid-houses, lately erected; and a span-roofed house, running north and south, 40 feet by 18 feet, divided into three compartments, the first being occupied by greenhouse flowering plants, the second by Orchids, and the third is a small propagating house. The stocking of these houses with plants has only been the work of three years and a half; and yet the collection, which is managed with great skill by Mr. Croucher, is one of the best in the country, and the admiration of all who inspect it. C. J.

Section of Mr. Peacock's Agave-house.

Materials for Glass-houses.—I am glad to see Mr. Baines's remarks (see p. 416), directing attention to the want of durability in modern hot-houses. I quite agree with him that red pine, and the redder or more resinous kind (or pitch pine, as it is called), is the proper timber for hot-house building. Pitch pine, owing to the resin it contains, is specially adapted for wall-plates, gutter-beams, stage-feet, and all parts exposed to the action of water. As to iron as a substitute for wood in horticultural buildings, it is best suited for ornamental conservatories and curved roofs, but is still too expensive for ordinary use. The principal cause of the great revolution that has taken place in hot-house building is the desire in the horticultural world for something new; it need not be meritorious, if it is only new; or even an old system under a new name has been known to give great satisfaction. A "tubular rib," a "patent curved structure," a "patent diaphragm," or a new system of glazing, each with a host of testimonials, showing it to be the best, are all acceptable to modern horticulturists. But the article must be cheap. A gentleman who intends erecting hot-houses, asks estimates from a number of builders, looks for the lowest offer, and accepts it, without taking into consideration either the quantity or quality of the work he is to get. A "Judicious combination of wood, iron, and glass for £6!" is what is wanted by many would-be horti-

culturists. If gentlemen, before agreeing with any builder, would go themselves, or send their gardeners to see houses already built by good firms, they would be better able to judge of the relative value of such offers. It may be interesting to mention that there are still one or two old-established firms in the country who build hot-houses of red and pitch pine only, all materials and workmanship being of the best kind, and the houses constructed with a view to durability, as well as to the admission of the greatest possible amount of light, and having the latest improvements in ventilation and heating. But what chance have such old-fashioned qualifications as efficiency and durability, against a dazzling throng of new patented inventions?—J. B., jun.

THE GREAT GARDEN AT HAMMA, NEAR ALGIERS.

THIS remarkable garden, founded by the French Government, a few years after the conquest of Algiers, is scarcely so well known as it ought to be in England. It was the work of M. Hardy, who has held the office of curator-in-chief ever since its creation—which was mainly effected by his own intelligent perseverance. The botanical riches of the garden of Hamma (placed, as it is, in a medium climate, where the plants of Europe and those of the tropics flourish with almost equal luxuriance, side by side), exceed, perhaps, those of any other botanical garden in the world, not even excepting that of Calcutta. It appears, however, that though so successful under the direct management of the French Government and the able directorship of the enterprising official, M. Hardy, that it is about to be leased to an Algerian company for a period of forty-nine years. MM. Talabot and Frémy, are at the head of this company; M. Talabot, in addition to his reputation as an eminent botanist, joined to that of an enthusiastic amateur horticulturist, is doubtless a fitting person for such a position, and under his energetic management the utility of the establishment will, as it should seem, acquire a great extension. The garden will be continuously enriched by the acquisition of new and precious plants, and the sale of such plants as may be desired by cultivators, either agricultural or horticultural, will be greatly facilitated, as a whole string of petty official regulations, often excessively irksome and vexatious, will be at once got rid of; while the large views of M. Talabot will be ably supplemented by the invaluable aid of M. Rivière, who has been appointed managing director. Nevertheless, M. Carrière, in the *Revue Horticole*, cannot help expressing fears that the future of the noble garden at Hamma, may not, in private hands, be as secure as it would have been had it remained an appanage of the Algerian Government. Others may eventually succeed to the management of the affairs of the company who may prefer money to science; and, should that be the case, all the sacrifices that have been made during the last thirty years may turn out to have been wasted.

The Symbolology of Flowers and Plants.—This has been in all preceding ages a popular form of superstition, and in some parts still continues to be so. On this subject a conference was assembled by M. Von Peryes, of Vienna, at which the popular beliefs and legends connected with the vegetable kingdom, and their probable origin and history, were discussed in a lively and piquant manner. But it is not necessary to go to Austria for examples of that kind. Who has not known old people in remote places, who have firmly believed that a tuft of Housleek on the roof is sure to bring "good luck," if not neglected; and that if washed off by heavy rain, or blown away in a gale, ill luck is sure to follow? And some such unsophisticated beings feel sure that a tuft of a certain kind of Grass on the house-top is a sure preservative against "thunderbolts;" many among such still prefer the remedies distilled from simple herbs, collected by some old shepherd, to the very best "medical advice."

THE KITCHEN GARDEN.

CULTURE OF BRUSSELS SPROUTS.

The Brussels Sprout is undoubtedly one of the best and hardiest of our Winter Greens, and ought to be found in every cottage garden in the country. Although nearly related to the Savoy, it is superior to that kind of Cabbage both in flavour and productiveness, and is at least quite as hardy. In the severe winter of 1859-61 I saw several instances where the Savoy had succumbed to the severity of the weather, while the Brussels Sprout had withstood it with comparative impunity. There are several varieties of it named in seedsmen's catalogues, but I think it is at least doubtful if they are really distinct. No doubt much has, and may still be, done to improve it by persistently carrying out a system of selecting seed from the best and most prolific plants only, and I do not know any vegetable that will better repay any extra care or trouble incurred in carrying this matter out in a thoroughly practical manner. In the north and cold wet districts generally, to have Brussels Sprouts in season from October to March, the first sowing should be made in October. Sow thinly on a warm south border, and when the plants come up thin them out to prevent them drawing each other up weakly; the thinnings may, if necessary, be pricked out. In October all seeds of the Cabbage tribe vegetate with the greatest certainty, and there is a strength and vigour about the young plants that is often absent from those raised from seeds sown early in spring. Whenever circumstances have prevented autumn sowing it is highly desirable, if the means are at hand, to sow a few seeds in a box in some spare corner under glass early in February, not necessarily in a warm house, as the plants will come up weakly, but in some cool airy structure, where they can be easily protected from the attacks of the many enemies to which early sown seeds in the open air are liable. There is, I think, no question that if Brussels Sprouts were sown earlier, and had, consequently, a longer time for growth, the result would be satisfactory. Sow again in the open air in March and also in April for use in spring. The first plantation should be made early in May, in order to give the plants time to attain their fullest development by October or November, and as they should, when full grown, be at least a yard high and stout in proportion, more space should be allotted to them than will be required for later crops; 3 feet will not be too much space between the rows, and 2 feet plant from plant. The demand must regulate the supply, but other plantations may be made at intervals when land becomes vacant till the middle, or, in warm situations, to the end of July, after which time—except, for instance, in a season like the present—they cannot be expected to attain a profitable size. In the matter of soil, Brussels Sprouts are not at all particular, provided it is well and deeply cultivated and fairly manured. Poor sandy soil will require a heavy dressing of good manure, whilst lime and burnt clay may be beneficially applied to cold clayey land in preference to rank manure just previous to planting, which would have a tendency to produce gross open sprouts instead of the close medium-sized buttons so much appreciated in the kitchen. Plant the successional crops as far as possible in different aspects—even altering the direction of the rows will make some difference; and a few should, if possible, be planted on the north side of a wall, fence, or screen of some kind. Frequent stirrings of the soil, general clean culture, and removing decaying leaves add to their growth and cleanly appearance, and ought to be insisted on. As regards earthing up the stems, I have grown them, both with and without that assistance, with much about the same result. In windy places, I should certainly recommend earthing up, in order to enable them to resist wind power; but, as Brussels Sprouts, unlike Cabbage or Broccoli, bear all up the stems, it is not desirable to bury them to any great depth beyond giving them necessary support. Do not cut out the Cabbage-like heart from the centre of the plant till the crop is fit for gathering; and, if a really good plant or two can be spared, save your own seed. The London market gardeners prefer, as a rule, stems of medium length, from which they think they get the hardest and best sprouts; with them, however, Brussels Sprouts are chiefly grown as catch-crops.

E. HOBDAY.

CULTURE OF BROAD BEANS.

THE Broad Beans, which are usually seen in Covent Garden and other London markets, come chiefly out of what are called the home counties. About Acton, and one or two other places near London, a few are grown for early purposes, convenience of cropping, or as a rotation crop; but otherwise they are not grown to any great extent close to London. The Early Mazagan, Broad Windsor, Green Broad Windsor, and the Long Pod are the sorts usually cultivated; and, as they are not a very remunerative crop, considering the great labour incurred in sowing, growing, picking, packing, and carting, before they are marketed, valuable ground is not occupied with them. Dry and light soils, in warm positions, are suitable for early sowings, which are commonly confined to the Early Mazagan, and made in January, and again in February, in rows 2½ feet apart, running across or obliquely in the borders or quarters. Large sowings of the Long Pod are made in the latter half of February and in March, in rows equally distant as for Mazagans, but with less particularity as regards the way in which they run, the position of the quarter, or the quality of the soil which they occupy. The Broad Windsors, which form the principal crop, are generally sown in March. Although the common Broad Windsor constitutes the bulk of the main crop, yet the Green Broad Windsor is usually preferred by consumers when they get accustomed to it. In proof of this, a market-gardener at Mitcham informed me that he generally grew several acres of the green sort; but one year, having got by mistake seeds of the ordinary Broad Windsor instead, he sowed them. When reaping time came his customers, one and all, complained of the inferiority of his Beans that year compared with those of former seasons. Ever since then, therefore, he has carefully avoided the objectionable kind, and has only grown the sort most appreciated, viz., the Broad Green Windsor. There are no important particulars connected with Bean culture, beyond the routine of rigid cleanliness, and nipping off the points of the haulm as soon as a fair crop of flowers is produced, in order to stimulate the pods and produce earliness. Beans are sometimes sown at the distances above named on ground occupied with Radish beds, with the progress of which they interfere but little, as the Radishes are too small to injure the Beans, and they are sure to be removed before the latter can be in any way injurious to them. Early Stone Turnips are not unfrequently sown between the rows of Beans, and such spaces are also sometimes occupied with Cos Lettuces, Cabbages, Cauliflowers, or Brussels Sprouts in every second row, Lettuces being in the intervening one. The Lettuces, being soon ready for market, are removed, and thus make a good clearance for a free circulation of air, and a passage from which the Beans off two rows can be easily gathered. Market gardeners seldom save their own seeds, as they find it cheaper in the end to buy them. When seeds are to be saved, the haulm is allowed to occupy the ground a few weeks longer than it otherwise would do, and thus curtails the chance of cropping it with Savoys, late Sprouts, or Cauliflowers, early Endive, and a few other crops. As soon, therefore, as the Beans have entirely yielded their crop, the haulm is pulled up and carted to the manure heap. The ground is then dug, or ploughed, or deeply worked without being manured, and a crop of Endive or white Cos Lettuce is planted therein for use in October, or Savoys, Brussels Sprouts, Cauliflower, Broccoli, autumn Radishes, or transplanted Leeks, may be planted in it; or, if it has been manured and deeply dug, it will be in good condition for a fresh Strawberry plantation. Some growers, however, grow Beans largely for seedling purposes only, and in this case about one-half or two-thirds of the pods, consisting of the earliest formed, are picked off for marketing in a green or usable condition, the remainder being left to ripen. If all were left, the seeds would not be so large, plump, or heavy as when the pods are thus thinned out. When the Beans have become well matured the haulm is pulled up, and laid on its side to dry for the remainder of the day, if fine; it is then tied into bundles, dried thoroughly, brought home, and either thrashed at once, or kept under cover or in a thatched stack until a more convenient season for thrashing out the seeds occurs. Coleworts form the chief succession to the seed Bean crop. Covent Garden Market is supplied with fresh Broad Beans from Algiers as early as April, and it is astonishing to see how well they bear their sea passage, and maintain their freshness until they arrive in London. France then furnishes supplies soon afterwards, and maintains them until home-grown produce comes in.

F.

Short v. Long Cucumbers.—Duke of Edinburgh excels all that I have tested as regards length, fruit of it having been grown to the extraordinary length of 40 inches. I have myself had it 31 inches. It somewhat resembles the Marquis of Lorne, but is, in my opinion, an improvement on the Marquis. I have always found that long Cucumbers require more heat than those of moderate length,

and the latter are the most useful. When grown to the length just indicated, it will be found that only one fruit can be grown on a plant at a time, and that such long varieties can only just be kept alive during the dull months of winter, while other sorts, such as Telegraph and Hedser Prolific can always be depended on to grow and fruit well. Telegraph can be cut from 18 to 24 inches, while Hedser seldom exceeds 14 inches. As regards prolificacy, there is not much difference between them. Telegraph, in my opinion, will outlive such sorts as Duke of Edinburgh, Marquis of Lorne, Blue Gown, and others. Again, few sorts keep their true character as well as Telegraph.—D. S. GILLET, *Court Garden, Great Marlow.*

Cucumbers in Russia.—On my way home from the fair [of Nijni-Novgorod] (says a correspondent of the *Daily News*), I was again struck with what I had often remarked before, viz., the profusion of Water Melons and Cucumbers, which were being everywhere offered for sale. Pyramids of Melons and Water Melons, like cannon-balls in an arsenal, were heaped up in every direction, and as for Cucumbers, you couldn't help fancying that a plague of Cucumbers, like Locusts, had descended upon the earth. All along the Volga, from Astrakhan to Nijni, the whole population seemed engaged in eating Water Melons. Their price being three sopeks, equivalent to one penny, put them within the reach of even the moderately wealthy. At every wood station that we stopped at, the Water Melon and its rival, the Sunflower, were the subject of a lively traffic. Saratov seemed to be the head-quarters of this latter fruit, but we had outposts all along the line. But if the Water Melon and the Sunflower are luxuries and pastimes, the Cucumber is a law and a necessity. You never see a Russian peasant at dinner but you see the lump of black bread and the Cucumber. A moujik's dinner may be said to consist of *r* plus Cucumber. The *r* will consist of his favourite Cabbage soup (*schtchi*), with or without meat in it, and sometimes in addition to it the equally famous grit porridge (*kascha*). Sometimes the *kascha* is without *schtchi*, and sometimes the *schtchi* is without the *kascha*, but whether in separation or combination, the Cucumber, at least, is always there; and should *r* equal zero, as I am afraid it sometimes does, then the ever-faithful Cucumber does duty for all the rest. Cucumber seems certainly a singular dish to be so national in a country with a climate like Russia's. It is the last that one would select *à priori* for the post; but this is only one of a great many singularities one meets with. The Cucumber costs the thirtieth part of a penny about the Volga; perhaps this fact will explain the anomaly.

THE ARBORETUM.

PLANTING FOR AUTUMNAL EFFECTS.

THE beauties of plant life in autumn may be fewer than such as herald the spring, yet they are none the less acceptable or worthy of our attentive observation. Nay, rather should we do all that is possible to lengthen and increase their effects; for all that can be done to make rural scenery in autumn effective, is so much done to reduce the length of dreary winter. Yet, even in the immediate vicinity of the mansion or villa, we find little attempted in the way of planting those trees and shrubs, which, in the closing days of the leaf's existence, display shades of colour so rich and profusely varied, as to be unequalled at any other season. Why such should be the case is the more remarkable, considering that while planting for autumn effect, we may leave the spring beauties undiminished. All that is required is to keep in view the double object of autumn as well as spring and summer colouring. This is not to be arrived at alone by selecting those deciduous trees and shrubs, which in the closing stages of their annual leafage, are adorned in shades such as the greatest painters can only feebly portray, but by a judicious selection, as well, of those that will retain to the latest period their healthy summer's green. The rage that has existed for Coniferous and allied trees during the last thirty years, has had something to do with the mistakes that have been committed, and are still being made in too many directions. The smaller and more confined the grounds, the more necessary is it to rely upon the effects produced within a prescribed space without any assistance from more distant objects, as in the case of a large domain, where such generally exist to aid the immediate surroundings. Yet even when Coniferous plants are largely grown in collections, as where a Pinetum is planted comprising most of the leading varieties, the space instead of being entirely occupied by Coniferae and Taxaceae, might be the better for a few such trees as Scarlet Oak, the leaves of which are so finely coloured; and Hornbeam, with its equally fine pale golden garb, habit, and colour, which contrast so well with the sombre tints of Coniferous trees. In the spring the Purple Beech is equally effective, as also the Red Acer. These are only a few of what might with advantage be introduced into the company of a Pinetum; the simple necessity being that

sufficient forethought is used in planting them in such positions, relatively to the other trees, as to produce the most telling effects, and at such distances as neither to interfere with, nor in themselves be interfered with, by those with which they are associated. This latter point is one that it might be supposed unnecessary to allude to, yet in the case of a great deal of planting, it would appear otherwise; for, even with trees intended to stand permanently, we often see them planted, not with a view to the room they will ultimately occupy, but so as to look best for the time being, or under forgetfulness that they ever would get bigger after planting. No greater error can be committed than this. What can be more provoking than to see a couple of trees, alike valuable in themselves, as also for the position they occupy, standing in such close proximity as to render the destruction of one of them inevitable? A short time since I saw a broad walk surrounding a Pinetum, with a row of noble Deodaras on each side, planted in opposite pairs, and so near that even the doing away with the walk on which they had far encroached, would only for a few years delay the removal of one-half of them. This mistake was evidently traceable to the desire of producing immediate effect by the position in which they stood in relation to the walk when first planted; and this is only one instance in hundreds that may be seen wherever we happen to turn.

There is another matter of which I would remind those who, with little discrimination, place reliance upon Coniferous trees for permanent effect in places where their destruction would cause a serious blank. It is fourteen years since the memorable frost of 1860-61 caused such havoc amongst numbers of such trees, which seemed likely, from the countries and elevations they came from, to stand our severest winters. Yet great numbers of them have since been planted, although we are pretty certain, sooner or later, to have a recurrence of such a frost; and the longer it is before it comes the greater gaps it is likely to make. In park planting little has been done in most instances to produce autumnal or spring effects, compared with what it is possible to accomplish by planting in the foreground such trees and shrubs as produce the best autumn tints. Where the land is naturally flat, it is in the foreground principally that this colouring can be introduced; not so where it has sharp undulations or gradually slopes towards the eye. In such situations much may be done by planting on the most elevated spots Oaks, Hornbeam, and Elm; these are always effective, but more particularly so when interspersed amongst considerable breadths of Pines. So associated, their effects are beautiful. Recently a good deal has been said about the effects produced by planting broad masses together of some particular tree in juxtaposition with similar breadths of others, each distinct in character, much after the fashion of a patchwork counterpane, made with extraordinarily large pieces. I feel the greatest reluctance in using the term unnatural, for it is the fancied vantage ground that every garden grumbler perches himself upon when he attempts to carry his argument out of the reach of ordinary mortals; yet the whole routine of cultivation in connection with the vegetable kingdom is necessarily so different from, and in most cases unavoidably opposite to, Nature's workings, that to instance Nature's own doings as a type for us to follow in these matters is simply an absurdity. Where the land forms a succession of hill and valley, with rugged bluffs and low sheltered spots, it is quite possible to plant varieties of trees in masses with good effect, provided very great care is taken that the outlines are skilfully managed. In such situations, fine effects of colour can be produced for all times of the year, as anyone may judge who has seen some of the work of the late Mr. J. C. Loudon on the high ground leading from the village of Cheadle to Alton Towers, the seat of the Earl of Shrewsbury. Yet it is in the immediate vicinity of the mansion—in the dressed grounds, more properly speaking—that the finest combination of spring and especially autumn leaf-colouring can be produced. Here, with judicious planting, the different shades of green, brown, yellow, and red can be so intermixed as to produce the best effects. What a splendid background the *Ailantus grandifolia* makes for the deep red leaves of the snowy *Mespilus*, which is one of the first to don its autumn livery, almost making us regret that it is not so coloured all the season; this, combined with its profuse sheet of spring inflorescence, makes it one of the best moderate-sized flowering trees that can be put into the shrubbery. And yet how many acres of ornamental planting is now done without a single *Mespilus* being introduced. As to the *Ailantus*, it seems strange that this most ornamental tree is not more generally planted; it has everything to recommend it, being a good grower, it is very distinct in foliage, which it wears until late in the season, and never affected by insects. Here, again, the autumn colours of the scarlet Oak and the Hornbeam are indispensable, backed up with, or near to *Pinus austriaca* and *P. Cembra*, with any of the varieties of Spruce or other dense green-foliage tree. The Spanish Chestnut is also distinctly coloured later on. As a plant for affording intense red

colouring early in autumn, nothing surpasses the Virginian Creeper (*Ampelopsis hederacea*), trained to stout 10 or 12-foot iron rods with double-clawed feet inserted in the ground, so as to resist the wind; dotted about the shrubbery, it has a fine effect whilst green early in the season, and doubly so in its autumn garb. So grown, these dense columns not only form a beautiful contrast to other things in colour, but also in form, to the broad sky line of such trees as the Cedar of Lebanon. One of the most beautiful and intensely coloured-leaved plants, as well as coming in when most of the others are fallen and gone, is the Guelder Rose (*Viburnum Opulus*). It is also well known as one of our most effective spring-flowering shrubs; but it is in the autumn, when it is more alone, as affording colour, that it is so valuable; its miniature Vine-like leaves are then seen to perfection; it also retains them longer in their highly-coloured state than most trees do. It is deserving to be much more extensively planted than it generally is. At intervals of a score yards on the front of the shrubbery it has a charming effect, combined with the dark foliage of evergreens. The above are a few of the trees and shrubs that, when used judiciously, are most effective, attracting our attention when it is less divided than in the gay summer-time's profusion of colours, which makes us more indifferent to the merits of individual plants through the numbers we then have to choose from.—*Fitch*.

PRUNING ORNAMENTAL TREES.

If you want bushes, not trees, do not prune. If you want trees, not bushes, let them be trained to a single stem. This remark applies, however, more to deciduous trees, than to Conifers. Most of the latter only push out lateral branches from the lowest part of the stem, and are thus feathered to the ground, without throwing up more than one main trunk. But deciduous trees, especially where they have sufficient room, frequently throw up two or three stems which rival each other, or strong shoots from the lower part of the stems, which become large branches in time. If the rival stems are not all excised but one, and if the branches springing low from that stem are not lopped off, no tree will then be formed, but only a large bush. Our remarks on pruning apply only to ornamental trees, and are directed purely to ornamental ends. The pruning of fruit trees is based on quite different principles, and is directed towards securing the largest quantity and best quality of fruit, quite irrespective of elegance of appearance. The main objects to be secured by pruning are—first, to develop a handsome and healthy main trunk, which is only to diverge into branches at a given height from the ground. Where trees are grown in close proximity to each other, as in woods, Nature performs the office of denuding the stems of their lower branches. When in such close contact, want of air and deficiency of light, combined with the mechanical effect of friction and the natural tendency of the sap upwards, cause the destruction of all but the upper limbs of the trees. But whilst in a spacious forest a multitude of tall branchless trunks, canopied over by foliage high over our heads, possess a beauty and majesty quite their own, such a feature in isolated specimens or in small clumps would lose its charm. Hence, in artificially divesting trees of branches at 6, 8, or 10 feet from the ground, you are to have regard to the lateral space you wish them to occupy, and the aspect which you wish them to present. The second object in pruning is to obtain a symmetrical shape by lopping off straggling boughs or branches, clearing part of the shoots that grow inside the head when they are too numerous, cutting away all dead wood and unhealthy growths, &c. In pruning a tree, cut away the branch which is to come away close to the trunk, and the bark will soon "callus" over and cover the scar. In forest-pruning, it is held that a branch should be amputated at a foot or more from the trunk, or else the excision will cause knots in the timber. However this may be as applied to forestry, it cannot apply to the pruning of ornamental trees; for nothing can be uglier than these "snags," as such projecting old stumps are called. In training young trees to a stem, do it by degrees year after year till you have denuded the stem as high as you wish. Some at once cut away all the lateral branches of a young tree, except a few at the extreme top of the sapling. Others do still worse. With a view of forcing an upward growth, they cut the side branches to within a few inches of the stem, leaving the ugly snags on to push a few weak twigs next year. The result of this treatment is that the desired upward growth is obtained with a vengeance. The stem hardly grows in thickness, the sap rises to the few uncut boughs at the top, and you get a tall, thin, weakly object, that will never form a tree at all. It becomes what is technically called "whippy," because it resembles a coachman's long whip, and the only remedy, if once the young tree has been pruned into that shape, is to take it up and plant another in its stead, which you must take care not to serve in the same manner. It is the growth of the side branches which promotes expansion in the diameter of the main stem,

and the lower ones must only be removed by degrees, when those higher up appear sufficiently numerous for the young tree to bear the loss of the lower ones with impunity. If a young bough shows a propensity to grow out of place, or to an undue length, so as to require repression, this may be effected whilst in a young stage of growth, by simply pinching off its extremity, thus arresting its further extension. The proper time to prune trees is between the cessation of their growth in autumn and the movement of their sap in spring. The amputation during summer of the woody parts of trees is injurious to them in many ways, and in many species produces a copious discharge of sap (termed "bleeding"), which considerably weakens them. But the process of trimming hedges, or (where there is a fancy for such things) clipping evergreens into fantastic shapes, is performed in summer, as this promotes a second growth from the parts that are left untouched, which makes the foliage and spray denser.

A. MONGREDIEN.

The Mountain Ash.—This, when laden with bright scarlet berries, forms a most conspicuous object in our landscapes. Indeed, its merits in this respect, are not sufficiently appreciated, for it is oftener found growing in out-of-the-way situations than as an ornamental tree. Like the Barberry, it delights in a somewhat strong soil and damp climate. Under such conditions its graceful foliage is luxuriant and green, and the berries large and bright. I remember being very much struck with the effect produced by the trees when in fruit, on one occasion when travelling between Hawick and Carlisle, in the valley of the Esk. In that locality it seems to be at home, for I do not recollect seeing such large and brightly-coloured berries as I saw on these trees, though, no doubt, it would do as well in any similar situation. The wood is also valuable for many purposes, so that there is some inducement to plant it. Its effect is most striking when planted in groups.—S. W. J.

New Lilacs.—These are announced in various quarters, and it is only surprising that there are not more of them; for the beauty of this grand early-flowering shrub is proverbial. Among the new varieties referred to, *Ville de Troye*, a dark flowered and late blooming variety, promises well; and *Rouge ponctué*, of very bright colour, is equally good. *Géant des Batailles* and *de Croneels* are both of them brilliant varieties. The blossoms of *Gloire des Monlins* are flesh-coloured, and said to be very fragrant; while *Aline Mockeris*, of dwarf growth and a very abundant flowerer, may prove extremely valuable for planting nearer to the front of shrubberies than the taller growing kinds. Notwithstanding all this wealth of novelty, one still finds the old kinds—the common broad-leaved (*Syringa vulgaris*), and the Persian or narrow-leaved kind (*S. persica*), being alone used (with very rare exceptions) in the planting of new shrubberies; even the magnificent and well-known variety, distinguished as *S. Lindleyana*, being, as yet, found in very few gardens, though procurable from any leading nurseryman.—WESTBOURNE.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

A Barren Walnut Tree.—Can any correspondent tell me of some means to make a Walnut tree bear? It is of large size, about fifty years old, and has always been very healthy, but has hardly ever borne any nuts.—*Jackdaw*.

A Pretty Combination.—I have just seen a little picture, formed quite accidentally no doubt, but none the less beautiful on that account. It consists of a low bush of the common Strawberry tree (*Arbutus Unedo*), covered with its pearly little berry-like bells, and nearly surrounded by a low hedge composed of *Cotoneaster Summervillei*, covered with its rich scarlet fruit.—*B*.

A Hardy Australian Shrub (*Leptospermum lanigerum*).—This is one of the few Australian plants that have proved quite hardy in England, and welcome for that, even if it possessed no other merits; but its fragrant glaucous leaves, its abundant white flowers, and copious crop of round, hard berries, form of themselves sufficient titles to our attention. We think that *Leptospermum ballatum* will also prove hardy, and we are engaged in experiments to ascertain the fact.—*Heathside Manual*.

Trees and Lightning.—A violent thunderstorm passed over Versailles in the beginning of last month, doing considerable damage. M. Berigny (in a note to the Paris Academy) draws the following conclusions from the effects: 1. Wherever lightning, in striking trees, meets neither branches nor knobs, it descends vertically, making a very distinct, and narrow groove, a few centimetres in width. 2. When it meets branches, it passes round them successively, and describes a helicoidal groove. 3. When it meets a strong knob, it stops suddenly and changes in direction, to go to near conducting bodies, sometimes in various directions.

Pines on Mountains.—The *Gardener's Monthly* states that the *Pinus flexilis*, which grows on the Rocky Mountains and the Sierras, attains a height of 130 feet on mountain sides which have an altitude of several thousand feet, but on the higher and more exposed crests of Mount Shasta and other peaks, it is reduced to a straggling shrub creeping on the ground. On the large trees the cones are 5 inches long; on the reduced ones only 1 or 2 inches. We see a similar result with our New England trees on the White and other mountains. At the foot of Mount Washington, the evergreen trees are 60 or 70 feet high, but an hour's ride up the cloud railway shows the same species as small as Currant bushes and flat on the rocks.

A GERMAN CHERRY ORCHARD AND TIMBER-BUILT DWELLING HOUSE.

OUR beautiful illustration, which is quite a little masterpiece of wood engraving in regard to careful definition and high finish, represents a German farmhouse, with its duck pond and its little bleaching ground, where pieces of homespun linen are being spread upon the soft greensward; it has much the character of a timber-built English farmhouse of that style of rural architecture which harmonised very pleasingly with the surrounding scenery; the angularity of the black timber work, and its sharp effects, in connection with the white plaster-work between, forming a desirable contrast with the soft gradations of colour and undulating lines of the surrounding landscape. Those timber and plaster-built dwellings are fast disappearing in England, even from our most outlying villages in the remoter parts of the country; and the genteel filtered-down imitations of them, which the architects of our suburban villas are setting up in many parts, do not satisfactorily supply their place.

beauty. In some of the eastern provinces, indeed, important buildings are constructed entirely of wood; even to railway stations of large dimensions, and the official buildings of the smaller towns. This system might be used with advantage in parts of England, where brick-earth is absent and Oak timber tolerably plentiful. Split into thin lengths of about 8 inches in width, after the manner of park palings, such slips of Oak form a very available material, and almost any kind of dwelling might be constructed with it. Buildings so constructed, as we know by the fresh and sound appearance of very old park palings, of this material, would be exceedingly durable; and their grey tone would harmonise well with the landscape. From the cottage, put together in the cheapest possible manner, to the spacious shooting box, rendered ornamental in a variety of ways, timber buildings of this class might be erected with advantage. Of the Cherry orchard immediately surrounding the pretty German dwelling, it may be observed that Cherry culture in

Timber-built House and Cherry Orchard.

In many parts of Germany, however, timber still plays an important part in the external walls of farmhouses, and the same ancient custom of colouring the timber black and the plaster-work white, also prevails, as shown in our illustration. There, too, however, the old timber-built manse is destined soon to pass away, and brick or stone, it is becoming evident, will eventually replace the external use of timber altogether; but in many parts of Germany this will be a slow process, for the Pine forests are so far from being exhausted (as they have long since been with us)—that wood, as the cheapest possible material, will continue for a time, in spite of all attempted innovations, to be largely employed for such purposes. In some of the more eastern provinces, indeed, wood is used for the roof as well as the walls, being split pieces of Pine, of about the size and thickness of tiles, and used exactly as tiles or slates are with us. With this material, many architectural features are wrought out in south-eastern Germany with great ingenuity and

cottage and farm gardens is very much neglected with us; and yet, wherever it is adopted, it is found to be profitable, to the extent of paying the rent. II.

A New Source of Indiarubber.—Among the various plants from which a juice is obtained suitable for the manufacture of Indiarubber, the *Sapota Mulleri* may be named. This plant is found abundantly in British Guiana; but, although its nature has been long known, from the wood having been very generally employed for building purposes, and on account of continual attention having been called to its profusely abundant sap, yet it is only quite recently that this sap has been utilised for commercial purposes. It appears to have been Mr. Melville who first suggested to English capitalists the commercial value of the sap of *S. Mulleri*, in the year 1860; and already the product is being largely exported under the name of *Balatagum*. This discovery is becoming important, as the true Indiarubber plant is said to be nearly exterminated by the reckless proceedings of greedy agents.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

Hardy Flowers, Alpine Plants, and the Wild Garden.

When to Cut the Plumes of Pampas Grass.—This Grass possesses a beauty which reaches far beyond its mere autumnal career in the garden, a beauty which is, in fact, persistent, that is, provided the spikes are cut in proper time. Nay, further, I am almost disposed to give it a use and purpose even beyond the mere ornamental—what more appropriate than to utilise it in lieu of those bunches of feathers for the purpose of removing dust from glasses, paintings, and other delicate ornaments? Its soft silky texture, and its length of stem combined, appear at once to give it an admirable adaptation for such a purpose. This statement will, no doubt, be met with an assurance from many that it is liable to tumble to pieces by a gradual process of disintegration, and its value in this way altogether neutralised. There is, however, a right time to cut it, by which this serious disadvantage may be altogether avoided. To fix this time as referable to a week or even a month would be an unwise procedure, so much depending on the season and also on the locality in which it is grown. It will, therefore, be better to take its state of development as the criterion by which to judge; every day that succeeds the full expansion of the panicle from the sheathing process in which, in its young state, it is folded, depreciates, in the first place, the purity of its silky texture, and, in the second, renders the possible fertilisation of its flowers, even though perfect seeds may not be developed—a serious detriment to its value, whether taken from an ornamental or utilitarian point of view. Be it remembered, also, that there is a considerable difference between the male and female plant; the former, though the more elegant, is much less persistent in its blossom than the latter; hence, the female plant is, by all means, to be preferred, added to which, the silvery character is much more pronounced. Having said so much about the bloom, let me put in my veto against cutting away the foliage after the flowering is over; this is something worse than a piece of vandalism. Not only are its gracefully recurved lines beautiful, even when coloured with the autumnal yellow premonitory of decay, but they constitute Nature's true protective covering against the snows and frosts of winter; any removal of the foliage should be done in spring, when, or rather just before, fresh growth commences. It should always be remembered that in its native habitat, frosts and snows are almost unknown; hence, we should not only be thankful for the wondrous adaptability with which it is endowed that enables it to withstand the many vicissitudes of our northern climate, but also assist Nature by all the means in our power. The foregoing remarks on the *Gynerium*, lead me on to say a word or two about another plant from the southern hemisphere, to which much of the autumnal gaiety of our garden is indebted—namely,

The *Tritoma*.—Not unfrequently have I seen the foliage of this plant cut off almost close to the ground, leaving the tender leaves at the heart bare of all protection, and, this too, at a time when the tissues are most liable to suffer; let every leaf be left intact until well on in the spring, when the sharp upright growth of the newly formed foliage indicates that vital activity is once more called into action, and then, and not till then, remove the foliage of the previous season. This is all the more necessary, seeing that there are *Tritomas* that flower in the winter, and, in fact, all winter through. Frequently have I seen the thick fleshy stems that have laid prostrate on the surface of the snow during a severe frost, rise again erect when the weather moderated; and, although not so brilliant by any means as the old *T. Uvaria*, still, produced in mid-winter, their flowers have a value that fully compensates for any deficiency in colour. It may be interesting to some of your readers to know whence arises this peculiar habit of winter-blooming in the *Tritomas*, and on this matter I think I can throw some light. Some twenty-five years ago, there were three species in cultivation, respectively known as *Tritoma Uvaria*, *media*, and *sarmentosa*; the two former were up to that time to be met with in a puny half-starved condition, in those conservatories where collections, rather than selections, were the order of the day; the latter, a by no means showy plant, had been relegated to the herbaceous border (in those days such a border did exist in all places that had any pretensions to the name of a garden; possibly its ancient prestige was waning, for, if I remember, at that time General Tom Thumb had taken the field with his fiery red coat, and not only threatened, but actually did, clear all before him); now this plant had two peculiarities, the first whence the specific name was derived, consisted in the fact, that a shoot or bud was developed from the side of each flower-stem, by which means the plant might readily be increased; the second was, that its period of blooming was so indefinite that it could only be specialised by saying that it bloomed all the year round. Let me here ask, do any of your readers possess the true old *Tritoma sarmentosa*? With me, I

regret to say, it is lost, no doubt it is to be found somewhere in the country, and I should much like to possess it once again—possibly this enquiry may enable me to find out its present location. At the time I allude to, when our so-called tender Cape plant was first turned into the open ground, and first enabled to prove its adaptability to our northern climate and soil, it was naturally associated with its congeners, and, as a cross, the old *Tritoma sarmentosa*—without losing its winter-flowering proclivities—improved in colour and size to that extent that the depreciation is usually attributed to a want of sun to bring out the incalescent character which the early autumn blooms of the true *Tritoma Uvaria* possess. That there are distinct species so called, beyond the three named, I very much doubt; I look upon them as merely variations, sometimes more *Uvaria*, sometimes more *sarmentosa* in character; and this, I judge from some forty or fifty seedlings originally raised and equally divided between the two parentages. These two plants, viz., the *Gynerium* and *Tritoma*, hold such an important position in the autumn decoration of our gardens that I think they are fully entitled to a special individualisation in the “weekly calendar.” There are but few plants from the south of the Equator to which the term hardy can be honestly applied, and, so far as the flower garden is concerned, most distinctly do these stand in the foremost rank.—JAS. C. NIVEN, *Botanic Gardens, Hull*.

Flower Garden and Pleasure Grounds.

The unusually mild weather experienced during the latter part of October and the early part of the present month has caused *Aubrietias*, *Primroses*, *Violets*, *Forget-me-nots*, and similar plants, to very considerably anticipate their usual time of flowering, and our gardens may almost be said to be already somewhat gay with spring flowers; Grass also continues to grow so much, that the mowing-machine can hardly yet be dispensed with. With the exception of the Oak, the leaves of most other deciduous trees have fallen, and a thorough clearing up is necessary, in order to remove worm-casts as well as fallen leaves; and, after all this has been done, all lawns and Grass belts should be well rolled, with a somewhat heavy iron roller, while the turf is soft and elastic; and, wherever the surface is to any extent irregular, the present is a suitable time to rectify such inequalities. Where little elevations exist, they may be, to some extent, forced down by the use of a heavy rammer, or turf-beater, and the turf should be removed from depressions, and soil should be introduced to raise them to the proper level, replacing the turf as soon as this is done; but, wherever considerable irregularity of surface exists, it is then advisable to carefully remove the turf altogether, and make the surface from which it has been taken perfectly level; and it can hardly, indeed, be rendered too solid. As soon as this has been done, let the turf be re-laid, beating it well down with a heavy turf-beater, occasionally rolling it during winter and spring when the weather will permit. Finish the planting of *Snowdrops*, *Crocuses*, *Anemones*, *Tulips*, *Squills*, and similar bulbous plants. The herbaceous ground, too, should now have a thorough cleaning, cutting down and removing all decayed stalks, together with the remains of annual flowers; *Dahlia* tubers, and the bulbs of the various kinds of *Gladioli* should also now be taken up, and, after being well dried, stored out of the reach of frost. Wherever improvements and alterations are in hand such work should now be pushed forward with all possible despatch, as the present mild damp weather is exceedingly favourable for the transplanting of trees and shrubs, as well as for the re-laying of turf, and of Box and other edgings. Many trees and shrubs may be readily increased by layering their lower branches, and the present is a suitable time for performing that operation. In cases where this may have been done about this time last year, such layers, will generally now be well rooted and should be removed from the stools, trimmed into form, and planted out in lines in the nursery ground, or wherever they may be required. This is a somewhat critical period for recently struck cuttings of *Pelargoniums*, and other bedding plants, and it may, in some instances, be quite necessary to assist partially-rooted cuttings with a little artificial heat, especially in the case of the various variegated and tricolour *Pelargoniums*, *Heliotropes*, the dwarf variety of the *Ageratum* (*Imperial Dwarf*), and the various *Coleuses* and *Alternantheras*, while the *Fuchsia*, *Verbena*, *Lobelia*, and several other kinds of bedding plants, being more hardy, may, if fairly rooted, be allowed to remain for some time longer in cold pits or frames.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

The question is often asked, “what Roses can I plant against my garden walls, which I want to look green as well as gay with flowers. Many varieties of Roses are evergreen, and in mild winters, with careful training, will cover a wall and look as neat as Ivy. It is not, however, advisable to use evergreen Roses altogether for wall-covering, as they only flower once, and then all is blank, with the

exception of green foliage for the season. The best plan is to intermix with some of the free-flowering climbing Hybrid perpetuals, Bonbons, Noisettes, and Teas, allowing the evergreen varieties to form the groundwork. Thus, instead of a blaze of beauty for a month or so, the flowering season will be prolonged from June till October, and if the autumn is mild they will last even up to November. For wall decoration, of this kind, prepare the ground well before planting. The evergreen kinds should stand about 7 feet apart, so as to allow 2 feet for free-flowering varieties. The best of the evergreen Roses are the following—Myrianthes, *Felicité perpetuelle*, yellow, Banksian, Fortunei, spectabilis, Princess Louise, Princess Marie, Donna Maria, Banksiaeflora, and Ophiric. Of Perpetuals, use General Jacqueminot, Jules Margottin, Maréchal Vaillant, Princess Louise Victoria, Princess Mary of Cambridge, Glory of Waltham, Duchess of Sutherland, Prince Camille de Rohan, Anna Alexieff, Sir J. Paxton (Bourbon), Climbing Devoniensis, Gloire de Dijon, and Maréchal Niel (Teas). It is best, if possible, to wire or cover a wall with lattice work, on which to train such Roses. Continue to get on with new plantations, and remove any beds of Roses that require moving this month. Protect all pot Roses from frost. Examine all Roses under cover; use a little sulphur where mildew still exists, and remove all bad foliage. It is best to dip or wash Roses that have been prepared for forcing this month, with some Gishurst compound, and if the pots are full of worms, use lime-water. Put a good sized knob of unslacked lime in four gallons of water; pour off the clear water, and use that for the purpose. It drives out the worms, and does not harm the Roses.—H. G.

Indoor Plant Department.

Chrysanthemums, placed amongst plants of an evergreen character, at certain distances apart, and properly arranged as to colours, give conservatories quite a gay appearance. Some of the Acacias are already beautifully in bloom, and even Fuchsias, planted in indoor borders, are yet well furnished with flowers. Those trained to rafters, and the bulk of pot-grown plants at rest, should be cut in. Zonal Polargoniums that were in pots all summer, and from which the flower-spikes were pinched during the autumn, should now be subjected to a moist warm temperature, in order to make them flower freely. Those which bloomed in early summer, and which were cut back early in July or the 1st of August, will come nicely into flower about Christmas, if placed in an intermediate temperature. Camellias and other evergreen plants still require water in considerable quantities. They should not, however, be deluged with it, but kept moderately moist. Some of the Tea plants in cool parts of conservatories are beginning to form dwarf evergreen bushes, and produce a profusion of pretty white Orange-like flowers. Dutch bulbs from the earliest potting are rapidly advancing, and should be kept in a moderate temperature. Succession ones should be kept under the stages of cool airy houses, plunged overhead amongst Cocoa-nut fibre. Cypripedium insignis, and a few other cool-house Orchids, should be introduced to the warmest part of conservatories; whilst Heaths, Mesembryanthemums, &c., should be kept in the coolest positions. In stoves a temperature should be maintained of 60° at night, with a rise to 70° by means of sunheat; the atmosphere, also, should be kept a little moist, as considerable injury is often done to both stove plants and Orchids by too dry an atmosphere in winter. During fine sunny weather the plants should be syringed about mid-day, in order that they may be quite dry before night sets in. Achimenes, Gloxinias, Caladiums, and herbaceous Begonias should be placed on their sides under stages, so as to be kept dry. Some of the Tydeas should be cut back and placed on shelves, but not kept absolutely dry. *Torenia asiatica*, one of the prettiest and most easily grown of stove plants, is in full beauty, and when grown in a basket suspended from the roof is very effective. Water Lilies, in some cases, should be cut over, so as to induce them to go to rest, and their room should be occupied by young Marantas and similar plants. Shoots of Stephanotis, Dipladenias, Allamandas, &c., should be spread out immediately below the glass in order to ripen the wood. *Ixoras* recently potted should be plunged in a little bottom-heat to induce fresh root action. *Franciscas* are coming prettily into bloom, and should be set on pots, above the level of the other plants, in order to show their beauty off to advantage. Some of the plants not wanted to flower so early should be removed to a cooler house. The different varieties of *Aschynanthus* are still gay, and form useful ornaments for baskets. Plants of *Eucharis amazonica* should now be subjected to a brisk bottom-heat, and have abundance of water, in order to induce them to flower. Plants of *Euphorbia jacquiniiflora* should also be liberally watered, and kept near the glass, in a brisk, moist, temperature. *E. splendens* and *Bojeri* look well, either on trellises or as wall climbers. They should be kept in intermediate houses and comparatively dry. Plants of *Curcumas* should be gradually dried off. The stems and leaves of

Gloriosa superba are now decaying, and the pots as soon as the bulbs are ripe, should be stored away like *Caladiums*.

Indoor Fruit Department.

The selection of varieties of Vines for renewing old, or for forming new, plantations in spring is an important matter which should not be neglected about this time. There is now such a variety of Grapes to produce fruit throughout the entire year that little difficulty will be experienced in choosing such kinds as will be suitable at any desired time and under all circumstances. The aim of the amateur cultivator should be to select such varieties as succeed best with the least attention. That many sorts succeed where others fail is often enough exemplified; Muscats, for instance, are not sorts which amateurs should plant, if success is expected to be attained with little care, or such as they can generally afford. As a black Grape, the old and well-tested Black Hamburgh is the best kind for amateurs to grow. It requires little more care than an ordinary green-house or window plant; it can be grown and ripened in perfection in favourable localities throughout the summer in any glazed structure without the assistance of fire heat—a matter well worth consideration now-a-days. Many kinds should not be planted in any one house for the mere sake of variety, as intermixtures are seldom productive of good results in the case of every sort. Those who only possess one house will do well to confine their selection to such varieties as succeed along with the Black Hamburgh. Amongst these Duke of Buccleuch, Buckland Sweetwater, Royal Muscadine, and Foster's White Seedling are the best. The first-named is an especially snitable companion for the Hamburgh. These varieties will supply fruit for at least five months of the year, that is, from June to the end of October, with very little trouble. Where only two Vineries exist, the second should be planted with late varieties to succeed those just named. For this purpose Black Alicante, Black Lady Downes, Gros Colman, and Gros Guillaume, are the best black sorts, among which preference should be given to the first two; as whites, White Lady Downes, Trebbiano, and the true Syrian are good sorts. Where a great many Vineries have to be planted, each variety should have a house to itself. The Esperione, which is one of the hardiest of all Grapes, does well in low ground Vineries. I may mention that in ordering good Grapes never wait until the last moment, as, where orders are executed in rotation, early ones have the best chance, as far as selection is concerned. Many prefer seeing and choosing their own Vines, and in such cases those with short-jointed nut-brown wood, little pith, and strong prominent eyes should be selected. Keep the ventilators of Vineries, in which Grapes are still hanging, quite close during damp wet days, and as the nights are now cold and damp, no air should then be admitted. Do not apply fire heat at night, unless the thermometer falls below 35°. See that no leaves or other matter likely to harbour or promote damp are allowed to remain in the same house in which Grapes are hanging. Coverings of mats or any woollen substance, should now be kept in readiness, for covering over the lights of Pine pits, when the nights are very cold; this not only saves firing, but is of great benefit to the Pines, as nothing is more trying or debilitating to their constitution than being subjected to a powerful fire heat.—J. Muir, *Clovenfords*.

Hardy Fruits.

Transplanting fruit trees has a tendency to cure sterility, and root-pruning is partial transplantation. The root is shortened, and, in virtue of that, its character and position are altered. The result of root-pruning is new roots and new root-runs, and in so far as it provides the latter, it is virtually a transplanting process; but we may also elect to transplant rather than root-prune. An examination of the state of the roots, may counsel a change of place and of food, and not a reduction of the number of roots. Roots made far from the surface are generally much different in character and in function from those formed near to it. Hence a tree may often be led into fertile habits, by simply raising its roots nearer the surface. Roots go instinctively where they will, if let alone. Encourage them to the surface by good food, and they will, as a rule, mount there after it, and abide and thrive amongst it. But worry them with other roots, or by deep-digging for other crops, and down they go. In all such cases the cultivator is bound to right the wrong he has done by bringing the roots up again—that is, by transplanting. The practice is mostly a cure for sterility for a time; but, if digging and cropping are again indulged in, the transplanting will need repeating again and again. Having brought up the roots, they should then be encouraged to remain near the surface, by leaving their bit of earth wholly to themselves. Nothing can exceed the short-sightedness of refusing to our fruit-trees a bit of ground wholly for the use of their roots. We build walls at great cost, skim meadows, and incur other heavy expenses in fruit-tree culture, and then spoil all for a crop of early Peas, Cauliflowers, or Potatoes, that any raised

bank or warm border would have grown as well or better. It is hardly worth while inducing fertility in trees through raising their roots near the surface, unless we are to let them remain there. One primary object of transplanting is to place the roots wholly in fresh soil. It is quite possible to remove the old and provide fresh material without changing the place of the tree; this transplants the roots, though the tree may occupy the same position as before. A tree may grow pretty freely and lack the power of fruit-bearing; but, place the roots in a good medium, and fertility follows, as a matter of course. This may also be done with very little root-pruning if skilfully and cautiously set about, and the roots in the new root-run will reconquer the loss incident to their destruction in a few months, and will hasten to multiply roots on all sides that will take short cuts to fertility.—D. T. FISH.

Kitchen Garden.

The mild autumn so far, which we have had, has been favourable to late-planted Lettuces and Endive; therefore, if ordinary precautions are taken to protect them from frost—and it does not require a very severe frost to injure Lettuce when full of growth—there will be for some time an abundant supply of salading. It often happens that there is a scarcity of good Lettuce after Christmas, from January till March, but that is a void it is not at all difficult to fill, if a pit can be spared now, with a hot-water pipe running along the front of it. If the pit has been used for Melons or Cucumbers, stir up the bed, or add a little fresh material to it; that will furnish a little bottom-heat by which the difficulty of supplying good crisp Lettuces in February may be easily surmounted. Select plants from the sowing made about the end of September; the Bath Cos is as good as any for the purpose, but there is no occasion to depend altogether upon one kind. Plant rather thickly, say about 6 inches apart, as, when the leaves meet, the largest heads may be tied up for use. About 6 inches in depth of any light rich soil will do in which to grow them; and the hot-water pipe will, without allowing it to get very hot, keep the air in motion, and maintain a healthy growing atmosphere, in which mildew will not easily effect a lodgment. This is the best, and in fact the only reliable way in our climate of producing good Lettuces in February. When the leaves will part readily from the crowns of Sea Kale, preparations may be made for forcing it, whenever it is desirable. It will force easily in the Mushroom-house, or in any other dark place, where a temperature of 55° or 60° can be maintained, and where the air can be excluded; or it may be forced where it grows, by covering with pots and fermenting materials; both systems have their advantages, and under certain given circumstances, both may be adopted. If the produce is required early, and it is decided to take the roots up to force, they should be lifted and just the longest ends cut off, which may be reserved for planting again in spring, and be laid in close together on the north side of a hedge or fence, from whence they may in suitable quantities, at intervals, be taken for forcing. On the approach of cold weather, observe, however, to cover them with litter, in order to keep the frost out. Rhubarb also, may be forced in much the same way. Medium-sized roots are best; they should be taken up as carefully as possible, and on no account should large roots be divided or cut about more than is absolutely necessary. Rhubarb-roots may be forced set closely together on a floor in any warm place, with only just sufficient soil to fill up the interstices between them. Do not let the present mild weather deter us from making preparations for frost; as it may now come at any time, have protecting materials ready for anything that may require covering; and as everything, in consequence of the mild growing weather, is gorged with sap, if sharp frost should set in, rather more care than usual will be necessary to keep all safe. There are various ways of protecting Broccoli, such as opening a trench on the north side of the plants, then placing a fork or spade on the south side, heeling them over carefully, and banking up the stems with earth; the upper part of the stems, where the heart springs from, is the most tender part of the plant, and that where protection is most required. Where the plants have had plenty of room to grow, say from 3 to 4 feet between the rows, and where there is, consequently, room to get in amongst them with the spade without injuring their foliage to bank the soil well up the stems, it will be a very great protection, and will not injure them in any way, whatever the character of the season may be. They may also, when frost sets in, have Fern or litter placed between them, and a little scattered lightly over them, but the latter should be removed when the frost is over, or the plants, or a portion of them, may be taken up with balls and planted in a more sheltered place. It should, however, always be borne in mind that any check of this kind now tends to reduce the size of the heads. The largest Turnips may be taken up to be prepared for frost; but the Black Stone will stand a good deal of frost without injury.—E. HOBDAY.

THE YOSEMITE VALLEY.

LEAVING Mariposa, our party, seven in number, thoroughly enjoyed the forest ride up the Chouchilla Creek, over the Divide, and down nearly 3,000 feet to the end of the stage road, the famous ranch of Clark and Moore, on the South Merced, a lovely, lonely, piney, primitive place. The Mariposa grove of big trees is about six miles from Clark's, up a trail somewhat rough, but leading through forests of great beauty. Many of the Pines along our way were of imposing breadth and height, but the first regular Sequoia gigantea we came upon was lying prone upon the earth, that had yielded to him when he fell almost as the sea gives place to the hull of a great ship. Grandeur and grander they grow, these sombre Titanic shapes, the longer you linger and look; and you feel that you will never quite pass out from the solemnising shadow that fell on you like that of the great past. Early the next morning we were mounted and away—eager for the Yosemite. We dined at Paragoy's the new half-way house. A few miles further, and we were on Inspiration Point, looking down on the mighty Mecca of our pilgrimage—an awful depth, whose vastness is wedded to unimagined brightness and loveliness; a sight that appalled while it attracted; a sublime terror; a beautiful abyss, the valley of the shadow of God. It seemed to me as I gazed that here was Nature's last, most cunning hiding-place for her utmost sublimities, her rarest splendours. Here she had worked her divinest miracles, with water and sunlight—lake, river, cataract, cascade, spray, mist, and rainbows by the thousand. There were arched and pillared rocks, so massive, so immense, it seemed they might have formed the foundation walls of a continent, and domes so vast, they seemed like young worlds, rounding out of chaos. By this trail you enter the valley near the Bridal Veil; and beautiful Pohono had dressed herself royally in rainbows to receive us. The sight of this fall, in the height of its summer glory, and the surpassing loveliness of the valley through all the five miles that remained for us to ride, charmed away fatigue. We forded countless streams, cold as snow and bright as sunshine; we passed through forests of blooming Azaleas and sweet Wild Roses and wondrous Ferns, grand natural parks of Oak and Cedar, groves and avenues of Locusts and Pines—indeed, of all sorts of trees, for the variety of foliage in the valley is wonderful. The Yosemite Falls proper, the entire descent of which is over 2,600 feet, are immediately in front of the Hutchings' Hotel, on the north side of the valley. Of course, from below you can see nothing of the Yosemite Creek. It looks as though it was a cataract from the start, born of the sky and the precipice. The roar of this king of waterfalls, in his grandest times, has a singular dual character—there is the eternal monotone, always distinct, though broken in upon by irregular crashes and booms, like gusty thunder. . . . The scene at the hotel on the morning of my second day was something memorable. The grounds and piazzas swarmed with tourists and guides, all demanding animals at once to make the excursions of Glacier Point or the Vernal and Nevada Falls. The more fortunate party, who got horses early, went to Glacier Point; others went to Nevada Falls, and had dinner there, and in the midst of it were called out of doors by the thunder of a great stone avalanche, which came down from the Cap of Liberty, and almost buried the hotel, and covered them with dust. They thought it was an earthquake, and wouldn't have missed it for anything. The rest of us finally straggled on one by one for the Bridal Veil, some on foot, some on horseback. Some of us found the place, others got lost. The party that got lost had the lunch basket. Glacier Point is on the south side of the Valley, 3,700 feet above the meadows. It is the point that gives you the finest comprehensive view of the Valley—especially of its upper waterfalls and rocks—with vast views of the High Sierra. All the great heights were pointed out to us—Mount Hoffman, Mount Lyell, Mount Dana, Mount Clark, and Mount Starr King. The vast view, from Glacier Point is the despair of poetry and art. Certainly its grandeur can never be compassed by the grandest sweep of human language. It is glory that must be seen; it is sublimity that must be felt; it is the "exceeding great reward" that must be toiled for. In our return journey we stopped at the Big Trees near Murphy's. The groves contain nearly a hundred of the giants. The tallest now standing is the "Keystone State," 325 feet. You drive past the stump and a section of the trunk of the immense tree felled several years ago. It was in its prime—only about 1,300 years old—and sound to the heart. Its fall shook the grove, as Caesar's fall shook Rome. It took half-a-dozen men with pump-angurs and wedges twenty-two days to do the dreadful deed. Over the stump is built a pavillion, dedicated to religious services, political meetings, dancing and tea parties. It is 32 feet in diameter. There is one dead tree yet standing, called the "Mother of the Forest." "Grant" is a solid, stately tree, 261 feet high. It seems perfectly sound and may stand a good 500 years, unless flayers, choppers, and angurs prove too much for it. The South Calaveras Grove contains more than a thousand Sequoias of stupendous size. GRACE GREENWOOD.

THE FRUIT GARDEN.

HUGE BUNCHES OF GRAPES.

Of the marvellous clusters of Grapes grown by Mr. Hunter, at Lambton Castle, we are enabled, through the courtesy of Mr. David Thomson, to reproduce the representations which appeared in *The Gardener*. The Vine which produced the largest cluster was struck from an eye in 1869. It bore six bunches the second year after planting, one of which Mr. Hunter staged in his first-prize collection in 1872. It bore eight bunches in 1873, one of these being the heaviest black Grape shown at Manchester, which weighed 13 lb. 4 oz.; while the smallest of the other seven weighed 4 lb. This year it has borne five bunches, one (fig. 1) 21 lb. 12 oz., one of 11 lb. 2 oz., of faultless symmetry, and the remaining four weighing 13 lb. 13 oz. In the same house grew a Vine of Raisin de Calabre, which bore a cluster (fig. 2) weighing 15 lb., and five others scarcely less; and there were also immense Trebbianos of from 10 lb. to 12 lb., Gros Guillaume of from 14 lb to 16 lb., very large Muscats, and Foster's Seedling of immense size and splendid quality. Mr. David Thomson assures us that the cluster of Black Hamburgh which weighed 21 lb. 12 oz. was not "brought about from fasciation or from the fusion of several bunches into one by natural grafting," he having inspected the bunch on two different occasions, and found it to be what gardeners term one distinct and separate "show" or bunch, with a main stem perfectly round, like any ordinary bunch, free from any fasciation or "natural grafting," as has been insinuated. All are aware that Black Hamburgh bunches assume all sorts of shapes, even on the same Vine. This was strikingly exemplified in the case of the Vine at Lambton. They sometimes come without any shoulders worthy the name; at other times they have shoulders nearly as large as the body of the bunch. The bunch in question was as remarkable for its curious shape as for its size, but it was one bunch, and the largest and heaviest yet grown. As to soil, it is the same sort that had been used for Grapes before these Vines were planted. It is a strong holding material; the Vines are grown at somewhat between 3 and 4 feet apart, up a long rafter of a 22 feet wide lean-to Vinery. The Vines are allowed to carry a very full complement of lateral growth and foliage, are very copiously watered and fed, and are remarkably strong and thick in the bole for their age. It is useless to suppose that as these Vines get older they will continue to bear such large bunches; but, fine as they are in berry now, we predict, if nothing happens to them, that they will improve in size of berry if they decrease in size of bunch.

(1) Black Hamburgh. (2) Raisin de Calabre.

PEARS WORTH GROWING.

THE following is a select and comparatively limited list of the Pears best worth culture, with a brief description of each, and some advice as to the care which each variety specially demands. I have been careful to name no varieties which do not possess undoubted merit with respect to quality, productiveness, and size. If a few of very small dimensions are found among them, they are either kinds which ripen at a time when others are scarce, or varieties in which smallness of size is amply made up for by the possession of some indisputable good quality. I do not condemn all other kinds not named herein, but have made a long-studied selection from among the best. I have followed, as far as possible, the natural order of the ripening of the fruit, first grouping together those that ripen in the same month; and, in the second place, arranging them in each month according to their respective early or late times of ripening.

July.

July brings us Pears once more. They are not yet such fruit as we shall gather in September and October, which will have acquired every perfection of quality and size, and the reason is very simple—the first fruits of summer have but little time to grow and ripen; those of autumn are longer nourished by the sap, enjoy for a longer time all the happy influences of heat and light, and have full time to come slowly to perfection; they are not hurried in any way. However, July Pears are not deficient in merit. In May and June we had nothing but the dry and leathery remnants of last year's crop, and now we have a supply of fresh, juicy, acidulous fruit, which deserves a hearty welcome from us. It is objected against these early fruits that they keep hardly any time, and the charge is partly true, but we must also confess that we are ourselves somewhat to blame in the matter. People generally do not know how summer fruits should be gathered; they wait until they turn yellow and fall, and then they set to briskly to collect them, but they are too late. The prudent gatherer makes several gatherings at different times; before the Pears are quite ripe he plucks a certain number, those that are most advanced, generally those on the lower parts of the tree; a few days afterwards he comes to those in the middle, and finally, some time later on, he gathers all the remainder. Adopt this plan; choose a fine day, when the fruit are not damp, and you will find that decay is generally supposed. The following four kinds we can recommend:

Summer Doyenne.—May be grown in all forms, but produces the largest fruit when grafted on the Pear-stock. Gather at different times, and always before the fruit turns yellow; otherwise, they will decay rapidly.

Beurre Giffard.—The best of the early summer Pears. It never succeeds on the Quince-stock; but on the Pear, and planted in good soil, it bears freely and plentifully, sometimes in the beginning of the month, and often ripens in the middle of August. A handsome and good sort. Gather as before.

Citron des Carmes.—This is welcome, as being the earliest Pear—the fruit that in the beginning of the month will adorn your table

with its handsome delicate green. If you wish to enjoy its best flavour, you must not allow it to hang on the tree till it turns yellow. It does best when grown as a standard in an open airy position; is vigorous, and an abundant bearer. Gather the fruit at different times.

Jargonelle.—Grown in an open airy position as a standard on a Pear-stock, this Pear will soon repay whatever outlay has been made for it. Gather at different times before it is fully ripe, and eat it immediately, if you want to enjoy its best flavour.

August.

Another month—no insignificant fraction of the year!—and our fruits are already increasing in size. At the end of the month, the difference is quite remarkable. Be as careful in gathering as before, and use the same method. Four more varieties.

Bergamotte d'Ete.—An old-fashioned Pear, which has been somewhat neglected, but unjustly so. It is said to become mealy, but this only occurs when it has been permitted to remain too long on the tree. It should be gathered at intervals, and while green; if allowed to turn yellow, it becomes insipid. When grown in any of the larger forms, it should be grafted on the Pear-stock, if a vigorous specimen is desired; if not, any other form will suit it; it adapts itself readily to all. For standards, the ground should be well manured. It is a very productive variety, and if grafted on Quince, should be pruned close.

Monsallard.—An excellent Pear, which has the good quality of keeping well for a summer fruit, and may be allowed to remain on the tree until it begins to turn yellow. May be grown in any form, and is very productive.

De l'Assomption.—A new Pear, not more than five years introduced, but one which we very strongly recommend as furnishing the connoisseur with a splendid dessert, and the grower with an article for market that will bring him in a large percentage on his outlay. It has a superior flavour, and is of large size—a quality rare at this time of the year; in addition to this, it keeps well. The tree is vigorous, and a good bearer. As a pyramid, it does better on the Pear-stock than on the Quince.

Williams's Bon Chretien.—Introduced nearly a hundred years ago—a good old age!—and, as yet, not a symptom of degeneration! This would be the pearl of summer fruits if it had not that strong musky flavour, which everybody does not like. This, however, may be considerably mitigated by gathering the fruit somewhat earlier; and, if it loses any of its good qualities thereby, it will still have quite enough left. We need hardly advise you to gather the fruit at intervals, otherwise you will never be able to enjoy the entire crop in a sound state, for it decays very rapidly. Does best as a pyramid on the Pear-stock.

September.

This month is so rich in fruits, that it is necessary to limit our desires in making a restricted selection. Abundance renders us fastidious, so we must enter on our list only those fruits that are pre-eminent in quality, and those trees that are very productive and of easy culture. We give seven varieties, which will satisfy most of these requirements. It must be observed that it is now becoming more difficult to particularise the exact time of ripening, as we find it either hastened or retarded according to the soil, climate, or temperature of the year, and mode of culture employed. Sometimes certain sorts will be ripe in the end of August, which, under different conditions, may be found green at the beginning of October. Your own observation will be necessary here.

Beurre d'Amanlis.—This excellent fruit may be enjoyed at the commencement of September. Gather at intervals, and do not allow it to hang until it is fully ripened, if you wish to keep it. This advice applies to almost all the fruits of this period. Does well as a standard, but must be planted where it will be sheltered from the winds. It is also adapted for almost any other form; but its wide-spreading straggling branches hinder it from making a good pyramid. It is hardy, very vigorous, even on the Quince-stock, and bears abundantly.

Flemish Beauty (Fondante des Bois).—This has long been known under the name of *Beurré Spence*, and has also had many other appellations. It is rather vigorous, and does well as a pyramid. The only fault which can be laid to its charge is, that it ripens, perhaps, rather fast. It should, consequently, be well looked after, and carefully gathered at intervals.

Doyenne de Meroide (Doyenné Boussoch, sometimes erroneously called *Beurré de Meroide*).—A very productive kind, but often deficient in vigour, unless it is grafted on the Pear-stock, on which it may be grown satisfactorily in any form.

Beurre Superfin.—It is generally a mistake to give fruits a high-sounding name. This is not the case in the present instance, for the Pear of Goubault has well maintained its early promise.

Not yet twenty-five years introduced it has made its way and achieved an excellent reputation. Most productive when grafted on the Pear-stock; it is a vigorous grower, hardy and prolific, and makes an excellent standard or pyramid.

Beurre Hardy.—Introduced about the same time as the preceding, it rivals it in the excellence of its fruit, and surpasses it in the qualities of fertility and of forming fine wood loaded with fruit-buds, suiting all climates, and adapted for all forms, but bearing off the palm for the splendid pyramids which it exhibits. In a word, it is one of the best fruits as well as one of the best trees. And yet, see what a task is ours! Neither *Beurré Hardy* nor *Beurré Superfin* are to be seen on the fruit-stalls which display such fine specimens (or, rather, such poor specimens) of inferior varieties. These two Pears (*Beurré Superfin* and *Beurré Hardy*) are handsome, fine, nay, exquisite, and yet many who are fond of Pears do not even know their names.

Beurre Gris (Brown *Beurré*).—This old Pear, which is more frequently called "*Beurré*" for shortness, the *Beurré par excellence*, the type of good melting Pears. Always good, it is, unfortunately, rather tender, and, as an exposed aspect does not suit its constitution, it will require the concentrated heat afforded by a wall. It does tolerably well on the Quince stock, but in most cases it succeeds much better when grafted on the Pear. The fruit is generally of a grey colour when grafted on the Pear and on vigorous stocks; in other cases it assumes a yellowish-brown tint, the parts exposed to the sun becoming bright red.

Louise Bonne of Jersey (Louise-Bonne d'Avranches).—Introduced eighty years ago; everybody knows this handsome elongated fruit, which displays its fine crimson colour in charming contrast to its green foliage. Nothing surpasses the effect of those long cordons of it which we see on our walls, or encircling door-ways and windows like climbing Rose trees. Nothing surpasses the quality of the fruit, which, moreover, ripens very gradually and keeps well. This is not all; the tree is suited for every form, grows as it ought to do, almost forms pyramids of itself, is hardy, and, on the Pear-stock, makes remarkably fine standards. Its blossoms, also seldom suffer during late frosts.

Seigneur d'Esperen (Fondante d'Automne).—A delicious Pear. Tree vigorous and very productive.

October and Beginning of November.

We find here some slow-ripeners of last month. We are now in the middle of autumn, and getting richer and richer, in varieties at least; there must be a limit to everything, and the quality of the Pears we have already named cannot be surpassed. The following are half-a-score of the best.

Beurre d'Apremont (*Beurré Bosc*).—We bow to the decision of Pomologists, but, to tell the truth, we regret the substitution of this name for the old one of *Beurré Bosc*, a name venerated by gardeners. It is moderately vigorous, but very productive; suited for all forms, but often does badly when grafted on the Quince. The fruit has the good quality of ripening gradually, and remaining a long time on the tree. Do not on any account confound this with the *Calebasse Bosc*.

Marie Louise.—There are trees of splendid appearance whose fruits are not worth speaking of, and the same may be said of a great many members of almost every family; but, in this instance, the reverse is the case. Here we have branches growing irregularly, and not much to please the eye, but these deficiencies are amply redeemed by the superior quality of the fruit. Does best when grafted on the Pear-stock.

Beurre Dumon.—Another fine fruit, very little known, but sure to make its way. It is very productive, and forms particularly good pyramids. It does well, moreover, in any form, and we shall be happy if we succeed in making it better known.

Van Mons.—Named by M. Léou Leclerc, in honour of the distinguished Belgian pomologist. We have already remarked, that all trees do not succeed in all soils indifferently; like ourselves they have capricious constitutions: therefore, if we do not want to be without certain excellent fruits, let us indulge the trees with their proper requirements. In the case of the Van Mons, unless under very exceptional circumstances, we should never graft it on Quince unless we wish to have a consumptive subject to nurse afterwards. We must use the Pear-stock, or else have recourse to intermediate grafting. This is effected by interposing another graft between the stock and the variety we wish to grow. It is employed when the stock does not supply sufficient vigour to the desired variety, and in this case we first graft on the stock some vigorous kind, such as the Vicar of Winkfield, the Jaminette, or the Conseiller de la Cour, and when this is well established we graft on it the variety which we desire to grow. To this the intermediate graft communicates its native vigour and the result is usually most satisfactory; with the Van Mons it

has proved very much so. You see a fruit-grower is not without ingenuity. When you have treated your Van Mons in this way you will have a productive tree which is sure to supply you with excellent fruit, whether grown against a wall with an eastern aspect, or in any of the smaller forms.

Doyenne Gris (Red Doyenné).—This would have been better named Doyenné Roux, as, like all fruits of a red colour, it is only grey when it is not ripe. An old-established fruit, with all the qualities of the white Doyenné, of which it is a variety, and to which it sometimes reverts; however, it is a better keeper and a better fruit on the whole. Does best on a wall.

Ne plus Meuris (Beurré d'Anjou).—An odd name to a very fine fruit. Grow it in any form you like, it answers well for all; but, for the larger forms, it almost always does best on the Pear-stock. In any form it bears abundantly, and ripens from the end of October to the end of November.

Soldat Laboureur.—An excellent fruit, which, like the last, ripens from the end of October to near the beginning of December. Some people lay to its charge a very serious fault, namely, that it soon falls from the tree, but, for our part, we have never known this to be the case.

Doyenne du Comice.—A Pear of the very first quality, native of Anjou, and scarcely twenty years introduced. When we have occasion to describe the different good qualities of the fruit, we are invariably obliged to make use of some superlative; indeed, its superior perfections may be the very reason that Nature appears to have struck a balance in the other direction by bestowing on the tree only a moderate degree of productiveness. However, it is a pretty regular bearer, grows naturally in pyramid form and sometimes attains the dimensions of a standard.

Beurre Clairgeau.—Always handsome. We wish we could also say without reservation "always good," but we must add that it requires certain conditions of soil; this should be calcareous or schistons. Moreover, we cannot too strongly impress upon you the necessity of growing it in a suitable manner. Never train it in any of the large forms, but either as a cordon or in columnar fashion. Do not graft it on Quince. On the Pear-stock it proves extremely productive, and you will have plenty of fruit-buds to spare for presents to any of your friends who may want them. Under the favourable conditions and treatment which we have indicated, the fruit will prove fine and melting, very juicy, and even perfumed. It is worth a little special attention and trouble to obtain such a fruit in all its perfection.

Duchesse d'Angouleme.—A fruit well known in every Pear garden. On the Continent it is met with in the streets, by the cart-load, as well as on the barrows of the fruit-dealers who dispose of very good-sized specimens at a reasonable price, a way of doing business that we should very much like to see extended to other varieties of Pears. There is a great diversity of opinion, or taste, with respect to this fruit, and everyone's opinion is generally in some degree well-founded. The whole question depends on what sort of soil the fruit has been grown on. If on a cold one, it will have neither sweetness nor perfume, and we need never expect it to be as juicy and melting as when it has had the benefit of good soil and a good season. However, everybody will admit that the tree is vigorous, and its fertility very great. Considering these two never-failing qualities, in addition to those which the fruit exhibits whenever it has had the advantage of favourable conditions, we do not think we should be justified in omitting it from the present list.

End of Autumn and Beginning of Winter.

Here we must discontinue noticing the time of ripening, as Pears at this season are very capricious in this respect. No doubt the time at which they are gathered, and the manner in which they have been previously treated, as well the greater or less degree of humidity of the season have a good deal to do with this; but sometimes without any assignable reason, and, as it were, by mere chance, some varieties ripen sooner than usual, and others, on the contrary, later. Accordingly the only information we can give as to the ripening of the kinds which follow, is that some of them often come to perfection at the beginning of November, while others are not fit for table until December or January. We venture to make a selection of eight of the best.

Bergamotte Crassane.—This is generally called "Crassane" for shortness, which has the merit of greater simplicity. A good old kind which everybody knows, of vigorous habit and succeeding well on the Quince-stock, but requiring a wall, with an eastern aspect if possible. The fruit keeps well, and is fit for table when it begins to turn yellow.

Figue d'Alencon (Figne).—Not so well known as it deserves to be, for we can recommend it as a Pear of first-rate quality. The tree is moderately vigorous, but it grows evenly, is productive, and suited

for all forms. If your ground is not wet, you may grow it as a standard on the Pear-stock.

Beurre Diel.—One of those whose time of ripening is uncertain; we have it fully matured at the end of October, and in some instances not sooner than the beginning of February. Temperature, aspect, and quality of soil influence all fruits, and this variety especially. Under a combination of favourable conditions it attains a high degree of excellence. The tree is very productive. Even on the Quince-stock it shows great vigour, and does well in any form; however, as its blossoms suffer more in late frosts than those of any other kind, it will be much safer on a wall. A first-rate fruit and a good keeper.

Passe Colmar.—A Pear which has everything to recommend it—the queen of Pears of this season, of all seasons, perhaps, and, as such, deserving of all the care and attention that our gratitude can suggest. It is adapted for all forms, even the standard; and, although not a very fast grower, is exceedingly productive.

Winter Nelis (Bonne de Malines).—A small fruit, but one that serves to show very emphatically that good qualities may be contained within small dimensions. It has a delicious flavour and keeps well. The tree is of moderately vigorous growth; it may be grown as a standard, but the fruit is then very small. In all cases it hangs for a long time on the tree. Remember, once for all, that before planting late varieties in open ground where they will be exposed to high winds, you should consider whether their fruit is sufficiently hardy. Do not forget that they have to hang longer than summer fruit, and that they will be exposed the greater part of the time to the winds of autumn.

Fondante du Panisel (Passe Colmar, formerly called Délices d'Hardenpont).—An excellent Pear. Tree rather vigorous, but of compact growth, very productive, suited for all forms, assuming of itself that of the pyramid.

Orpheline d'Enghien (Beurré d'Arenberg).—It is only fair that this Pear should have some fixed name. The name which we have given it is that which it bore for a long time amongst us; then, on an objection raised by the Belgians—an ill-founded objection—the Pomologists named it Beurré d'Arenberg; afterwards, on an objection raised by the French—a well-founded objection—the Congress restored its baptismal title, Orpheline d'Enghien. The Belgians persist in their error, but that is their own affair. This is a first-rate fruit, ripening from December to February. The tree is exceedingly productive, but not of strong growth; consequently, it is best adapted for the smaller forms.

Beurre d'Hardenpont (Glu Morcean).—Another amended name. This is what nearly all of us used to call Beurré d'Arenberg, in spite of the expostulations of the Belgians, who were right this time, and to whose nomenclature in the present instance we submit without the least hesitation. This Pear has every good quality, except one (perfection is so rare!). As soon as the young fruit begins to "set," a certain number turn yellow, fall off, and disappoint the hopes which their numerous blossoms had raised. This defect we wish to point out candidly, and it is one which occurs chiefly in warm localities. The entire crop does not perish, it is true, and the portion that survives this critical period does much to repair the misfortune. While it is young, it might be said that the tree took a malicious delight in disappointing the cultivator, and seemed as if it would never be productive; but, once it has reached a certain age, its really fertile character displays itself, increases rapidly, and is maintained to the end. It is also vigorous, and grows evenly. The fruit keeps well, and may be allowed to hang until it is quite yellow. It is to be observed that this Pear does well in cool soil, where its fruit loses nothing of its quality. It is the Pear of all others for northern climes. Against a wall, with an east or south aspect, it is perfect, and does not exhibit the defect which we have alluded to; it does well, indeed, against a wall with any aspect.

St. Germain d'Hiver (St. Germain).—An old well-known French fruit—one of those that require a certain amount of attention; for which, however, it afterwards makes a plentiful return. A few favoured growers succeed in bringing it to perfection in the open ground; but it almost always requires a wall, in which position the tree is productive, grows vigorously, and yields delicious fruit from November to February. It is yellow when ripe, and keeps well.

We have now come to the end of our treasures, to the latest Pears. They do not commence to ripen before February, and they sometimes keep till March, or even April. You will be told that there are some, even among those we are about to mention, that last longer, and that may be met with in May and June—we were very near saying in July. This may be possible, no doubt, but it is excessively rare. We can, however, direct you how to keep them still longer: Gather them very early, in September, for instance, and you will succeed, only don't imagine you will ever have fruit fit to eat. No; even rats themselves would not touch them; and, though

you may keep them for a year or more, they will never be a bit the riper. The period of gathering the fruits of this season is very important; leave them on the trees as long as you can, provided there is no appearance of frost. It is not sufficiently known how much is added to the quality and size of the fruit at this time of the year by allowing them to hang two or three weeks longer. The following is a choice selection of eight varieties:

Olivier de Serres.—This is a Pear that you have, perhaps, never yet met with. It has only been a few years introduced, but those who have got it know how much may be set down to its credit. We can recommend it strongly as one of the best winter Pears. It hangs well on the tree, and does not seem to care about the winds. Of rather vigorous growth, and adapted for pyramid or columnar form.

Josephine de Malines.—A delicious and excellent Pear, although not very large. Succeeds well as a pyramid, but much better as an espalier, or against a wall, when it also attains a greater size. Under favourable conditions the tree is fertile and vigorous; produces abundantly, but does not come very rapidly into bearing.

Passe Crassane.—A newer Pear than the preceding, and much larger, introduced in 1855. An excellent fruit, and one which we should be glad to see in general cultivation; unlike some other kinds, it never begins to decay at the heart. Ripens in March. Tree of moderately vigorous growth.

Doyenne d'Hiver (Easter Beurré).—An old, well-known, and much-cultivated Pear, generally very productive, but almost always requiring a wall, and a warm soil. Do not forget our recommendation not to gather it until quite ripe. It is well known that it is a good keeper and can be enjoyed for a long time; in winter it is the ornament of the table and the delight of the palace, but most of us have to regret the fact that in unsheltered, cold, and northern positions, it is difficult to obtain any fruit that is not spotted and speckled and unrepresentable. Some cultivators recommend the following remedy for this: In the month of August or September, graft on vigorous-growing and sound-wooded stocks (such as Beurré Diel, Catillac, Jaminette, &c.), fruit-buds of the Doyenné d'Hiver, and your crop will be all that you can desire. We have heard some persons laugh at this; but, for our part, we think the voice of those who have had experience in the matter should have more weight than the voice of those who merely ridicule what they have never tried. Let them make the experiment; and if they find out then that the advice is bad, they will have plenty of time to retaliate as much as they please.

Colmar d'Hiver (Glon Moreeau).—One of our old varieties, which should not be lost sight of. Rather slow in coming into bearing, but very productive when it once begins. It requires a wall and a good aspect. A fruit of first-rate quality.

Bergamotte Espéren (Espéren).—A fruit which the French are beginning to export, and we hope our foreign friends will never send us a worse one. An excellent Pear when the season is favourable, succeeding best against a wall. Tree very hardy, and, when grafted on the Pear-stock, does well in any of the larger forms. It is also of vigorous growth and very productive. One of the best late Pears and an excellent keeper.

Bergamotte Fortunee (Fortunée).—We have reflected seriously before entering this variety on our list. As a dessert fruit, it is often objected against it that it has too much acidity, ripens badly, and, consequently, becomes wrinkled in keeping. These objections are sometimes well-founded, but, at the same time, we are not ignorant that the defects alluded to will disappear when the tree is cultivated under favourable conditions—that is, in a light well-drained soil, in a warm position against a wall. In such auspicious circumstances the fruit attains an excellent quality. It is one of those fruits which we recommend to be gathered as late as possible; we believe that, in many cases, too early gathering is the cause of many of the complaints which are made against it. The tree is of tolerably vigorous growth.

Bon Chretien d'Hiver (Winter Bon Chretien).—The most ancient of our Pears. Some antiquarian writers would even refer it to the time of the deluge. It is a tree which requires some attentions; it must have heat, the support of a wall, and a south or west aspect. It grows vigorously on the Quince-stock. As a dessert fruit it is not to be despised, though, for cooking, it is perhaps more to be recommended.

Pears for Cooking.

In the matter of fruits good for cooking, the greater number of dessert Pears which possess a rather firm texture, and especially those of the winter months, might be employed with advantage. People generally, as may be supposed, reserve them for the table; they might, however, be much more used in the other way than they are at present. A great number of winter Pears are hardly good enough for dessert use, and seem to be specially destined for the

kitchen. In addition to the winter Bon Chretien, which we have just described, we desire to mention only the following three sorts, which, we believe, will amply supply every need.

Martin Sec seems expressly designed for pastry and confections of all sorts, in the preparation of which it requires little or no sugar. Tree, hardy and productive, well adapted for a pyramid, but usually grown as a standard. An excellent stowing Pear, in use from November to January.

Catillac.—An excellent, handsome, large Pear, and a first-rate keeper. Tree, very vigorous and productive, and succeeds admirably as a standard, notwithstanding the great size of the fruit, which frequently become enormous when grown on a wall, in which position this Pear also acquires a splendid colour.

D'Abbeville.—A Pear, but little known, as fine as, or even finer than, the last-named, hanging well on the tree, which is vigorous, productive, and forms an excellent pyramid.

People like to be directed when they are in doubt, and the precise object of these notes is to instruct those who are in that condition. We think we shall help them by pointing out in special lists the varieties which are best adapted to the various forms of growth. We shall thus save them the trouble of referring to the previous descriptions. Each series, as will be seen, contains Pears of all seasons, but they are always placed in their order of ripening.

Selection of Pears for Standards.

Citron des Carmes (on Pear-stock)	Beurré d'Ananlis	Beurré Diel
Doyenné de Juillet (Summer Doyenné), (on Pear-stock)	Beurré Hardy	Passe-Colmar
Jargonelle (Epagne) (on Pear-stock)	Louise Bonne de Jersey	Bonne de Malines (Winter Nelis)
Bergamotte d'Été (Summer Bergamotte)	Beurré d'Apremont	Josephine de Malines
Williams' Bon Chretien (on Pear-stock)	(Beurré Bosc, on Pear-stock)	Bergamotte Espéren
	Marie-Louise (on Pear-stock)	
	Doyenné du Comice (Comice)	Martin Sec
		Catillac
		D'Abbeville.

Not many late Pears, as will be seen, are in our list of standards. Experience has taught us, that the good winter Pears do not succeed in this form, and that it is only when grown on a wall, that most of them produce fruit worth speaking of. We should therefore reserve a portion of our walls for them, to the exclusion of other varieties, which will do pretty well in the open ground.

Selection of Pears for Pyramids.

Doyenné de Juillet (Summer Doyenné) on Pear-stock	Beurré Superfin	Bonne de Malines
Beurré Giffard (Giffard, on Pear-stock)	Beurré Hardy (Hardy)	Fondante du Paisel
Monsallard	Louise-Bonne de Jersey	Beurré d'Hardenpont
De l'Assomption (on Pear-stock)	Seigneur (Espéren)	Olivier de Serres
Williams' Bon-Chretien (on Pear-stock)	Beurré Dunois	Josephine de Malines
Fondante des Bois (Flemish Beauty)	Ne plus Meuris (on Pear-stock)	Passe-Crassane
Doyenné de Merode	Soldat Laboureur	Doyenné d'Alençon
	Doyenné du Comice	(Easter Beurré)
	Duchesse d'Angoulême	Bergamotte Espéren
	Figue d'Alençon	
	Beurré Diel	Martin Sec
	Passe-Colmar	D'Abbeville.

The Pears mentioned in this list will also serve for espaliers, a form of growth which we recommend as suited for the beds which run parallel with the walls. They are easily trained, and do not cause much shade; the fruit grown on them is not exposed to be blown off by the winds, and, as both air and light have free access to all parts of the tree, the crop becomes much finer and better. For an espalier you may also add Beurré d'Ananlis, which we do not recommend as a pyramid, on account of the straggling divergent growth of its branches. The Beurré Diel also has somewhat of this habit, but in a less degree. One word of advice. In gardens of some extent, when you plant on both sides of a walk, place the different kinds so that two trees of the same sort may be opposite each other. You will thus be less likely to have uneven growths, which are so offensive to the eye.

Selection of Pears for Walls.

We indicate the aspect usually most favourable for each.

Beurré gris (south and west)	Beurré d'Hardenpont (east and south)	Doyenné d'Alençon (south and west)
Van Mons (east)	Saint-Germain d'Hiver (east)	Bergamotte d'Espéren (south and west)
Doyenné Gris (east)	Josephine de Malines (south and west)	Colmar d'Hiver (south and west)
Bergamotte Crassane (east)	Passe-Crassane (south and west)	Bergamotte Fortunee (south and west)
Beurré Diel (south and west)	Easter Beurré (south and west)	Bon-Chretien d'Hiver (south and west)
Orpheline (east, south, and west)		

In this list we have purposely been sparing of the eastern aspect, as we would recommend that position to be reserved for other kinds of fruits. If you desire to plant Pear trees on the north side of your walls, you should select summer kinds in preference. In this case refer to the list of pyramids. If, however, you are short of

walls with other aspects, and your ground is dry rather than moist, you might plant on the north side winter Pears, with the exception of the last three on our list of wall Pears, as these require a strong dose of caloric to ripen them properly. Remember, however, that the soil being of equal quality, the fruit will not be so good here as in any other position in the garden.

Selection of Pears for Columns.

With the exception of the Bergamotte Crassane (Crassane), Colmar d'Hiver (Hou Morceau), Bergamotte Fortunée (Fortunée) and Bon-Christien d'Hiver (Winter Bon-Christien), which are seldom productive when not grown on walls, it may be said that this form is adapted for all varieties. In light soils, the preference should be given to the most vigorous growers, such as—

Monsallard	Beurré Dumon	Beurré Diel
Beurré d'Amanlis	Soldat Laboureur	Beurré d'Hardenpont
Beurré Hardy	Doyenné du Comice	Bergamotte d'Espéren

If, on the other hand, the soil is rich, and you do not wish for trees of great height, we recommend the following varieties, which are not vigorous growers, or only moderately so:

Citron des Carmes	Doyenné de Meroles	Figue d'Alençon
Doyenné de Juillet	Beurré Superfin	Passe-Colmar
Epargne	Louise-Bonne of Jersey	Bonne de Malines
Beurré Giffard	Seigneur (Espéren)	Fondante du Panisel
Bergamotte d'Été	Marie-Louise	Orpheline d'Enghien
De l'Assomption	Van Mons	Olivier de Serres
Williams's Bon-Christien	N plus Meuris	Josephine de Malines
Fondante des Bois	Beurré Clairgeau	Passe-Crassane
(Flemish Beauty)	Duchesse d'Angoulême	Doyenné d'Alençon

Selection of Pears for Horizontal or Oblique Cordons, or for closely-cut Forms.

Epargne	Louise Bonne of Jersey	St. Germain d'Hiver
Beurré Giffard	Seigneur	Fondante du Panisel
De l'Assomption	Marie Louise	Orpheline d'Enghien
Williams's Bon-Christien	Van Mons	Passe Crassane
Fondante des Bois	N plus Meuris	Easter Beurré
Doyenné de Meroles	Beurré Clairgeau	Doyenné d'Alençon
Beurré Superfin	Duchesse d'Angoulême	

Observe that we have here indicated the finest fruits and trees of only moderately vigorous growth. As we remarked in the case of those selected for columnar training, you may, in light soils, substitute in place of these the more vigorous varieties which are there mentioned.

F. JAMIN.

Ripening Pears Artificially.—Pomologists would scarcely recognise that noble Pear, the Beurré Superfin, when gathered some weeks before ripening, and placed on a moderately warm fire for say a fortnight or three weeks. Wishing to get up a few specimens of this Pear for a particular purpose, I gathered them before they parted readily from the parent stem, and placed them under the conditions just named, and the result has been fruit altogether unlike the same kind when allowed to ripen more naturally. They were indeed, superfine, melting, and excellent. Some Pears are well known to require an analogous process of ripening; but I never met with a variety upon which this artificial ripening process produced such marvellous results. That type of a melting, buttery Pear—the Marie Louise, and that delicious fruit the Winter Nellis, on the other hand, ripen as perfectly on the shelves of the fruit room as anywhere else. Speaking of Pears, I may say that we have had and have in these gardens immense crops this year. For example, on one tree of the Beurré d'Amanlis, covering no more space of wall than 12 feet square, I had the curiosity to count the Pears, and found them to number 500.—WILLIAM HUDSON, *Chase Cliffe, Derby.*

PERSONAL.

WE are pleased to announce that Mr. John Gibson, jun., has been appointed to succeed his father in the important charge of Hyde Park and Kensington Gardens.—The Metropolitan Board of Works have accepted Mr. J. Meston's tender for re-modelling Southwark Park. Mr. Meston is also engaged in improving the following open spaces, viz., Shepherd's Bush Common, London Fields, and Stoke Newington Common.—Mr. F. L. Olmsted, the designer of the Central Park at New York, is engaged in laying out the enlarged grounds of the Capitol at Washington.—Mr. B. S. Williams furnished many fine Tree-Ferns, Palms, Dracæas, and other plants, for the decoration of the Guildhall on Lord Mayor's day.—Mr. Denham is retiring from the management of the gardens at Broom's Barn Park, where he has been gardener to the Duke of Roxburgh for more than thirty years; his successor is Mr. William McKelvie, the indoor foreman at Floors Gardens.—Mr. Bain has from ill health again resigned the curatorship of the College Botanic Gardens at Dublin, which is now directed by Dr. Wright.—Mr. W. E. Rendle is to do the glass portion of the Westminster Winter Garden.—Mr. Brotherton retires from the management of the gardens at Argyle Lodge, Wimbledon, and takes charge of the Earl of Haddington's gardens at Tynningham, East Lothian.—Mr. James Anderson has commenced business as a nurseryman at Meadowbank.—Dr. Moore, of Glasnevin, has been appointed joint examiner in botany with Dr. Perceval Wright, in the School of Medicine, Trinity College, Dublin.—Next year's "Carter" Cup, value fifty guineas, and other prizes, for vegetables, offered by Messrs. Carter & Co., are to be awarded at the meetings of the Royal Horticultural Society in 1875.

"NOTEWORTHY HORTICULTURISTS" AND "BRITISH GARDENERS."

CAN you tell me, Mr. Editor, what is the difference between a "noteworthy horticulturist" who is a gardener, and a gardener who is a noteworthy horticulturist? Not being accustomed to hair-splitting questions, I have got mystified over this problem, until like John Bright's Skye-terrier, I am unable to tell which is the head or which is the tail. I am induced to put this question to you and your readers at the present time, as I observe a contemporary, with a knack of cultivating popularity with the fraternity, has undertaken the onerous responsibility of classifying the craft upon what may be called the "artificial system" for the time being; though it is exceedingly doubtful if all the species will ever be satisfactorily identified. In fact, I doubt there are some important members of the group that cannot be reached by the proposed system of arrangement at all. I observe, your contemporary divides the genus into two classes—a first class composed of "noteworthy horticulturists;" and a second, and, as I suppose, an inferior class, who are only "British Gardeners." Evidently this is not a natural arrangement, and is sure to be an unpopular one. Indeed, I am surprised that some of the genus have already been found willing to conform to this arrangement. I see no reason why one family should not include the whole group. The "noteworthy's," so far as they have been enumerated, include such excellent varieties as Chiswickiana, Kewensis, Gibsoni, Mooreana, M'Nabiana, and a number of others interesting chiefly in a botanical sense, and including some rather obscure types. Those named are all well-known, very worthy and popular kinds. Holeana I may mention as being of a robust character, and quite a unique and highly ornamental variety; M'Nabiana is another accomplished kind, but has lately appeared to suffer from some mysterious climatal influence; Gibsoni, too, is deservedly admired by all, and the others are possessed of good qualities: but none of these present features sufficiently distinct to warrant their being separated from a number of closely-allied genera, including some very notable members, such as Turnbullii, possessing no second-rate status, and celebrated for general good qualities, and the excellent strains which have been derived from them—types of the species, in fact, whose transmitted good qualities have become impressed in a marked manner upon the whole race, and whose names will occur at once to the minds of anyone having the least acquaintance with horticultural history. Why, therefore, this partial and unauthorised classification of an already well-understood species? It is to be regretted that the whole subject has not been more maturely considered, and the work taken up and executed in a comprehensive and popular manner. The only feature of the work under notice which meets with my approval is the separation of those having only a botanical interest from the cultivated varieties. Many of the former are unassuming enough in habit; but, as a rule, they are scrambling and weedy, and thrive but indifferently, except when backed by the garden varieties, and then they are exceedingly rampant, and sometimes parasitical in their habits, facts which have led some to suppose them to be a mere offshoot or "sprout" from the old garden stock—a supposition which gathers strength from the fact that they are characterised more by the absence than possession of many characteristics common to the latter. Be this as it may, however, should the gallery of "B. G.'s" go on, I would suggest the following concise method of description as being comprehensive and to the point. Class 2. History, struck as a cutting at A (date); potted off at B (date); planted out at C (date); thriving or otherwise; double or single; number of Olive branches; how trained; nourishment, including stimulents, found most serviceable; present health; and lastly, price, and if for sale. The whole might afterwards be catalogued for future reference.—HORTUS BRITANNICUS, in *The Gardener*.

The Agave a Cure for Scurvy.—General Sheridan, whose pacification of the Indian border is telegraphed officially by Sherman, is, according to the *Pall Mall Gazette*, by no means new to the hardships of frontier duties. It was not against the red men whom he has lately brought to order that he won his first laurels, but in combating the havoc of disease among his own little command, when, as a very young officer—the General is now but forty-five years old—he had charge of a small isolated post on the Texas border. Scurvy in its most serious form attacked his men, and there was no supply of vegetables or lime-juice to be had. But Sheridan had heard from an army surgeon that the juice of the Mexican Agave possessed the same anti-scorbutic properties. He organised a little expedition to go southward in search of it, and a grove of this plant being discovered about a hundred miles off, a good supply was procured, the juice expressed, and the men compelled, though not without many wry faces, and some protests, to take it in liberal doses. From that time the disease was effectually stayed.

THE LIBRARY.

VAN HOUTTE'S "FLORE DES SERRES."

THE fourth and concluding triple part of the twentieth volume of this beautifully illustrated work contains the following plant portraits, most of them well and delicately coloured, but not, on the whole, so interesting as the plants figured in this work usually are. Plate 1, *Bertolonia Van Houtte*, a new seedling variety of this highly ornamental but delicate family, raised in the establishment of Mr. Van Houtte, of low growing, or rather trailing, habit, and with large leaves of a deep green richly veined with deep rosy-purple, which has been awarded the first prize for new plants at all the great shows in France and Belgium to which it was sent during this year, and to the great beauty of which this plate is said to do no kind of justice. Plates 2 and 3 represent a most beautiful *Camellia*, *Madame Ambroise Verschaffelt*, of large size and most fully double flowers of white colour, most beautifully streaked and flaked with crimson; it is also said to be extremely free-flowering. Plate 4, *Camellia Festiva del Grande*, a beautiful deep red variety, distinctly dotted and tipped with white, and with shell-like regularity in the arrangement of the petals. Plate 5, *Camellia Giardino Santarelli*, a most exquisite variety, the outside petals being pure white and the centre of the flower deep clear rose colour, forming a most distinct and lovely contrast. Plate 6 represents *Lilium dalmaticum*, the black *Martagon* from Montenegro, which was so exceedingly rare till introduced in considerable quantities by that indefatigable collector and traveller, Herr Max Leichtlin, of Baden Baden. Plate 7 represents *Linaria alpina*, a rather pretty little rock plant, but hardly of sufficient importance to deserve illustration in such a work as this. Plate 8 represents *Statice Bonduelli*, a yellow-flowered variety from Algeria, introduced to this country by Mr. Thompson, of Ipswich, which should be almost hardy, or do with only a slight protection in the winter. Plate 9 is a portrait of *Schomburgkia Lyonsi*, an apparently free-flowering white variety of this family, sent to Messrs. Rollisson, of Tooting, by Mr. Lyons, who discovered it on the mountains of St. Anne, in Jamaica; it requires the temperature of a stove. Plate 10, *Salvia Gesneriiflora*, a handsome scarlet-flowered variety, said to hold its blossoms much longer than the more generally known *S. fulgens*. Plate 11, *Pentapterygium rugosum*, also known as *Vaccinium rugosum*, a greenhouse shrub, sent to Messrs. Veitch, of Chelsea, by their collector, Mr. T. Lobb, from Bootan, and producing bell-shaped flowers of a greenish-white faintly streaked with red, more curious than ornamental. Plate 12, *Lepanthes Calodyction*, a curious little Orchideaceous plant, introduced from the Andes by Mr. Spruce, with small veined leaves, producing from their axils extraordinarily shaped flowers of deep crimson-yellow colour, which is said to be in all probability now lost to European collections, being extremely difficult to cultivate or keep. Plate 13 represents a rather ornamental bright golden-flowered Composite, known under the following various names:—*Craspedia glauca*, under which it is figured in the *Botanical Register*, t. 1,908; *Craspedia pilosa*, according to Sprengel; *Craspedia Richea*, according to Cassini, which name is adopted by Mr. Vann Houtte; and *Podospermum pedunculare*, according to Siebold, in his "Plants of New Holland." It has bright glaucous foliage, surmounted by large blossom heads in the shape of golden balls; it requires the protection of a cool greenhouse, and is easily propagated by cuttings. It is indigenous to Van Dieman's Land. Plate 14, *Corylopsis spicata*, one of the introductions from Japan of Messrs. Siebold & Zuccarini, and figured by them in their "Flora Japonica," t. 19. It is one of the Nut family, and is said to produce before the leaves appear, in the early spring, numerous catkins filled with yellow Cowslip-like flowers. But we think that this plate gives the idea of a far more beautiful thing than this plant really is. Plate 15, is a portrait of *Cattleya maxima*, one of the most beautiful varieties of this lovely family, and producing large flowers of a pale rose colour, beautifully suffused with white, and an exquisitely veined throat and lip. It is also known under the name of *Epidendrum maximum*. Plate 16, represents the well-known hardy climber from Chili, *Berberidopsis corallina*, whose deep green foliage and profusely produced bunches of deep rose-coloured blossoms, make it in every way so desirable a plant for training up the side of a house, or to a garden trellis. Plate 17, A most beautiful Hybrid Perpetual Rose, named *Mademoiselle Annie Wood*, of a fine deep rose colour, and most fully double, likely to be a grand acquisition. Plate 18, A curious, but hideous, green-flowered Orchid, with a black lip, named *Calogyne pandurata*, somewhat the same combination of colours as are to be found in the flowers of *Iris tuberosa*. Plates 19 and 20, An extremely handsome and showy yellow-flowered Orchid, *Oncidium ampliatum majas*, the underparts of the petals being pure white, makes it also ornamental from behind, and it is said to be of easy culture. Plate 21, a pretty

greenhouse trailer, with bright pink tubular flowers, with a pale yellow throat, and known under various names, as *Tecoma mirabilis*, *T. Valdiviana*, *T. Guarume*, under which name it is figured in the *Botanical Magazine*, t. 4,896, and *Campsidium chilense*, according to Seeman, and as figured here by Mr. Van Houtte. Plates 22 and 23, represent the white form of *Azalea sinensis*, with much smaller flowers than the type, but very free-blooming. Plates 24 and 25, are a re-production of a plate in the *Floral Magazine* of July, 1874, of one of Mr. Bull's double red *Primulas*, which, if anything like the picture, should be fine indeed. The first quarter of the twenty-first volume is promised by Mr. Van Houtte, before the end of this month.

W. E. G.

Beauty in Common Things, illustrated by Mrs. J. W. Whymper, is a very pretty drawing-room table book. The twelve sketchy pictures of some of our old favourites of the banks and hedges of our country lanes are treated in a broad, artistic manner, altogether free from the minute kind of prettiness generally found to prevail in gift books of this kind. The Wild Strawberry, with its flowers and fruit, is effectively treated, and we recognise at once the touch of the same pencil that produced the popular Christmas cards, also chromo-lithographed by Mr. Dicks, the reproducer of the present little pictures. The group of Mushrooms (*Agaricus campestris*), is another well-treated picture sketch; and so also is the branch of Apple blossom. The descriptions are all that are required to furnish the names of the plants, and to bind together the dozen pretty little pictures into the required form of a gift book.

Pear Synonyms.—Since the publication of his history of Pears, M. André Leroy has issued a notice to his subscribers to the effect that the thirteen Pears named below are identical with those bearing the names cited:—

1. Abbé Pérez	is the same as	Virgouleuse.
2. Angobert	"	Manquette Double.
3. Arbre Corbé	"	Amiral.
4. Bergamote du Bugey	"	Bergamote de Paques.
5. Beurré Caty	"	Orpheline d'Engbien.
6. Bonne de Soulers	"	Bergamote de Paques.
7. Colmar Charui	"	Léon Leclerc Epineux.
8. Doyenné	"	Doyenné de Saumur.
9. Doyenné Sentelet	"	Doyenné Commun.
10. Duc de la Force	"	Bellissime d'Hiver.
11. Duchesse de Brabant	"	Soldat-Laboureur.
12. Henri Bouet	"	Doyenné Commun.
13. Saint-Augustin	"	Vernusson.

THE *Revue Horticole* for November, has a fine plate of three varieties of annual *Chrysanthemums* (*C. carinatum*) of the new double kinds—a white, a blush, and a pale orange variety, being figured. These new border flowers, perfectly hardy, and of compact habit of growth, will become highly valuable during the early summer months, before German Asters appear; while later sowings will produce plants flowering at the same time as the Asters, among which no shades of yellow or orange are found; and, consequently, the double yellow annual *Chrysanthemum* will prove a great acquisition, and furnish a striking contrast to the blues, lilacs, and reds of the Asters.—H. N. H.

OBITUARY.

PROFESSOR JAEQUEMYS.

IN the October number of the *Bulletin d'Agriculture*, published at Ghent, the death is announced of Professor Edouard Jacquemys, president of the Provincial Society of Agriculture of Eastern Flanders, and member of the Commission for the Encouragement of Agriculture in Belgium. M. Jacquemys died on the 31st of August, at his chateau of Menderhout, in the sixty-eighth year of his age. His various works on rural chemistry, and on the general principles of improved cultivation, are well known. His name is also closely associated with all recent attempts to improve the status of agricultural labourers, and to raise their position in the social scale. When it was proposed by the city of Ghent to establish a town district entirely composed of dwellings for horticultural and agricultural labourers—M. Jacquemys, who had recently erected a number of detached dwellings specially adapted to the wants of such a class, opposed the proposition in the following remarkable words:—"We have often had to listen to the remark that the labourer finds himself entirely isolated, among the different classes of organised society, as though he were a pariah. To lend official sanction to this too well-founded observation by building a town district entirely devoted to the dwellings of horticultural and agricultural labourers would be the consecration of that allegation by the erection of a permanent monument. The labourer must not be thus forced into exclusive contact with his own class alone, which would tend to discourage him, and unwholesomely curb that legitimate ambition which engenders ideas of order and economy; while contact with the superior artisan, who has once been a workman himself, and risen to a higher position by industry and economy, cannot but produce a salutary effect upon his character."

FLOWER BEDS AT THE CRYSTAL PALACE.

THE following are representations of two of the carpet beds which have been so much admired in the grounds of the Crystal Palace, during the past season. This system has much to recommend it, especially as it is so useful during the later part of the summer and autumn, after

the Pelargoniums and Calceolarias have done flowering. Our engravings show the manner in which these are planted better than any description. As will be seen, the colours were brightly contrasted with each other, and these beds, which we had an opportunity of seeing

on several occasions, were very beautiful and effective in every way, and may serve as examples for intending planters next season. I propose to send you some other plans of the beds in these grounds, which were so well-arranged this season by Mr. Thomson.

Kensington Gardens.

N. COLE.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 14TH.

THIS exhibition—the last of the present season—was unusually interesting. Chrysanthemums, both in the form of plants and cut blooms were well represented, and the show of fruit was undoubtedly the best of the season, especially as regards Apples and Pears. The vegetables too, which competed for Messrs. Carter & Co.'s prizes were all of remarkably fine quality, as were also the Potatoes and Celery, shown for comparison, from the Society's garden at Chiswick, and also the collections of Cabbages and Beets, exhibited by Messrs. Carter & Co.

Chrysanthemums—These were for the most part remarkably well grown, and effectively staged in the centre of the conservatory. Mr. J. Douglas, of Loxford Hall, had the best Pompous, and most remarkable specimens they were, being profusely flowered, and, what is of equal importance, they were well furnished with fresh foliage down to the pots. Among them the following varieties were especially good, viz., Lilac and white Cedo, Nulli, James Forsyth, a brilliant bronze, and very effective; Golden Circle, yellow; Helene, rosy-lilac; Aurora Borealis, a distinct variety of a rich warm brown colour; President, purple; St. Michael's, rich golden yellow; Madame Montell, one of the best of the Anemone-centred class, having a white ray and a golden disc; Saloman, bright lilac; Brilliant, rich crimson, in the way of, but scarcely so effective as Bob, the latter being a deserved favourite with all exhibitors; associated with these was Antonius, a distinct Anemone-flowered variety, with a golden ray and bright orange disc; these were compact shield-shaped plants. Mr. Harding staged half-a-dozen cone-shaped specimens remarkably well furnished; and Mr. Butcher, of the Priory, Hadley, near Barnet, had a well-grown group, in which a plant of Andromeda was conspicuous; this variety is of a decided lemon-yellow colour, and very effective. Mr. Fox, Old Charlton Gardens, Kent, had the best standards, prominent among which were Sunset, a rich bronze-tinted variety and Madame Martha, a good white. Of large-flowered, or show varieties, the dozen specimens staged by Mr. James, gardener to W. F. Watson, Esq., of Isleworth, were models of skilful culture. Among them the following were in every way excellent, viz., Mrs. Hallibarton, creamy-white, a fine full incurved flower; Jardin des Plantes, a bright yellow, not to be beaten either in foliage or flower; Julia Lagravere, a rich crimson, in the way of Bob, but larger; Faust, purple; Empress Eugenie, fine flesh; Mrs. G. Rundle, white golden; Eagle, rich bronze; and Lord Derby, bright purple. Mr. Hall, gardener to W. Stevens, Esq., Springfield, Brixton, furnished a well-grown collection, conspicuous in which were Gaucusey Nugget, lemon-yellow; Prince of Wales, maroon, shaded with silvery lilac; Mr. Gladstone, a fine incurved bronze; and Mrs. G. Rundle. Messrs. Cutbush & Sons, in addition to a fine collection of vigorous well-flowered specimens, showed a splendid plant of Mr. G. Glenn, a soft golden yellow sport from Mrs. G. Rundle; and Messrs. Dixon, of Amhurst Nursery, Hackney, had a good plant of Mrs. Rundle, unusually well flowered. Mr. J. Douglas staged a well-grown plant of the latter variety. It is worthy of note that many of the exhibitors failed on account of their plants being badly trained. Cut flowers were well represented. Mr. E. Smith, of Bristol House, Putney Heath, carried off the first prize with some splendid flowers, among which were the following viz., Alfred Salter, a fine rosy-lilac; Golden John Salter, a fine bronzy-yellow; Empress of India, white; Venus, fine lilac-purple; White Venus, and Lady Slade, the last a fine lilac flower. Mr. J. H. Hinnel also staged some splendid flowers, a trifle past their best, while Messrs. Cutbush & Sons had a splendid stand of twenty-four blooms.

Orchids.—These were not so well represented as we have seen them; but both Messrs. Veitch and Williams contributed some rare and valuable species. The first-named exhibitors had *Barkeria Lindleyana* var. *Centrae*, a charming winter-blooming plant; *Masdevallia amabilis*, a slender-growing species, of dwarf habit, with crimson flowers, and a white variety of *Odontoglossum Reezlii*; the last is very beautiful and a worthy companion to the white variety of *Lycaste Skinneri*. Mr. Williams had a fine plant of *Oncidium lanceanum* in perfect health, and several well-bloomed plants of the beautiful bright rosy-flowered *Calanthe Veitchii*. A splendid plant of *Vanda cœrulea* was shown by Mr. Smith, gardener to C. Lane, Esq., Badgemore, Henley-on-Thames. It was in the most perfect health, having two "leads," and bearing five spikes of delicate mauve-tinted flowers. The same plant was exhibited last year with four spikes, on which were thirty-eight flowers, this year the total number is sixty. Although by no means the largest, it is nevertheless, one of the most perfect examples of good cultivation we have seen, and what is important to amateurs it has been grown in a cool plant stove along with ordinary tropical decorative plants.

Miscellaneous Subjects.—Mr. B. S. Williams contributed a splendid group of Orchids, Palms, and other fine foliage plants, including *Ficus Parcels* and *Adiantum gracillimum*, to which we elsewhere refer. Messrs. Henderson exhibited flowering plants of *Sonerila Hendersoni* and its silvery-leaved variety, both bearing delicate lilac flowers with yellow anthers. The same firm also staged a fine orange-scarlet *Tritoma*, erroneously named *caulescens*, it was probably *T. Rooperi*; Mr. Green, of Reigate, who also staged the plant, informed us that it is invaluable for winter conservatory decoration. A collection of tree Carnations, sent by Messrs. Henderson, were much admired, and, indeed, few plants are better suited for winter vases and bouquets. Mr. Clarke, of Twickenham,

inaugurated the Cyclamen season by exhibiting a splendid batch of richly-coloured varieties, while Messrs. Standish & Co. and Mr. Turner staged some well-flowered *Bouvardias*. Mr. Turner also furnished an interesting collection of *Ivies* in pots.

Fruit.—Grapes were well represented, the principal exhibitors being Messrs. Lane, Mr. Moredith, Mr. Wildsmith, and Mr. Cole. Messrs. Lane had splendid bunches of Muscat of Alexandria and Muscat Hamburgh. Mr. Moredith had Gros Guillaume (Barbarossa), weighing 6 lbs. 4 oz., and Trebbiano, weighing 4 lbs. Mr. Wildsmith furnished a splendid bunch of Gros Colman, 5 lbs. 12 oz. The same exhibitor had three fine clusters of Lady Downe's, the total weight being 8 lbs. 11 oz., and the quality in every way perfect. Pines were limited in quantity, but the quality was above the usual average at this season. Mr. G. Ward, gardener to T. N. Miller, Esq., Bishop's Stortford, staged a fine symmetrical fruit of Charlotte Rothschild; and a splendid pair of smooth-leaved Cayenne came from the Royal Gardens at Frogmore, where this useful variety is grown largely. Pears were especially fine, some of the specimens of Uvedale's St. Germain (Belle Angevine) weighing from 3 lb. to 4 lb. each. The principal prizes for Pears went to the Jersey growers—a circumstance which caused considerable dissatisfaction among English growers. Separate classes should be formed for foreign produce. One English grower, Mr. Scott, of Merriott, had half-a-dozen splendid well-coloured specimens of Uvedale's St. Germain, weighing together 16 lbs. Dessert Pears of fine quality came from Mr. Langelais and Mr. Pluck (both Jersey Growers), Mr. Thomas, and Mr. G. T. Miles. The last-named exhibitor had half-a-dozen dishes of splendid quality, which were considered by many to be the best Pears shown. The following varieties were exhibited in splendid condition—viz., Chaumontelle, highly coloured, from many exhibitors, the Jersey specimens being the largest; Beurré Diel and Glou Moreau, both well-known kinds. Doyenne du Comice from several growers, large and fine, and there were nearly a dozen splendid dishes of Marie Louise, all in a state of remarkably good preservation for the season. Duchess d'Angoulême was, in one or two cases, very fine, Mr. Miles's dish of it being superbly finished. Beurré Bosc, Hughs's Victoria, Van Mons, Leon Le Clerc, Duc d'Angou, Easter Beurré, Beurré Batchelor, and Matthews' Eliza, were well represented, together with others too numerous to name. Apples—both dessert and kitchen varieties—were large and fine. The principal prizes for collections of dessert kinds went to the Jersey growers, who had, in some cases, remarkable specimens. In the first prize collection were superb examples of Court Pendu Plat (of which, however, one English grower, Mr. Welsh, of Caleot, had a single dish still finer) and Blenheim Orange, large and richly coloured; Ribston Pippin and Golden Russets were also very fine; in this class, for half-a-dozen varieties, Mr. C. Ross, gardener to C. Eyre, Esq., of Newberry, had some splendid fruit, his dishes of Blenheim Orange, Golden Reinette, Cox's Orange Pippin, Margil, and Scarlet Nonpareil, being remarkably fine. Single dishes were well represented, and some wonderful fine examples were shown of Ribston, Court Pendu Plat, King of the Pippins, Golden Pippin, and Margil. Kitchen Apples were altogether excellent; Mr. Rutland, Goodwood, staged a collection of eighteen varieties of excellent quality. Among these were highly-coloured Wellington, Blenheim Orange, Lincolnshire Reinette, Flower of Kent, Nelson's Glory, and Norfolk Boeling. The heaviest dish of six Apples came from Mr. C. Haycock, who showed Belle Dubois, weighing (the six) 5 lbs. 12 ozs., and Mr. Bailey, of Wimbledon, had Reinette du Canada, six of which weighed 5 lbs. 11 ozs.

Miscellaneous Fruits.—Mr. Sage, of Ashridge, sent a splendid cluster of Bananas in fine condition, the fruit being of a bright golden colour, and richly perfumed. Mr. R. Gilbert, of Burghley, exhibited a handsome Apple named Beauty of Barnack, and a bright scarlet fruited Solanum, which promises to be useful for winter decorative purposes. Mr. Earley contributed fruiting branches of an improved Bullace Plum, which will be useful for preserving purposes. Mr. Jas. McDonald sent a large Quince-shaped seedling Pear named Gloria Mundi, and Mr. Pearson, of Chilwell, furnished two dishes of Grapes, Chilwell Alicante, a distinct black variety, of good flavour, having compact bunches, and oblong berries. A white variety raised from the same parents as Golden Queen, and named Mrs. Pearson, received a certificate. Mr. Wells, of Redhill, sent an exhibit of Prince Albert Pear, a splendid variety, delicious in flavour; and Mr. W. Gardiner, of Easington Park, Stratford-on-Avon, sent a fine seedling Apple with tender juicy white flesh.

Vegetables.—These were excellent in quality, Potatoes, Celery, and Cabbages being well represented. Messrs. Carter & Co., had a fine collection (sixty-six varieties) of Potatoes not for competition, including nearly all the best varieties in cultivation, and a still larger collection of 110 varieties came from the Royal Horticultural Society's Gardens at Chiswick, together with a named collection of Celery. The prizes offered by Messrs. Carter, were well contested by three exhibitors. Among these Mr. Pragnell, of Sherborne Castle, Dorset, had London Flag Leeks, good Cardoons, Model Potatoes, Savoy's, Carter's Dwarf Mammoth Cauliflower, Giant Rocca Onions, very fine, James' Intermediate Carrots, and Supreme Tomatoes. Mr. Osman, of Sutton, had also a good collection, consisting of Savoy's, Beet, Trophy Tomato, Salsify, Scorzonera, Leeks, Turnips, and Potatoes. Mr. Lumsden's Cardoons were very fine, as were also his French Beans and Tomatoes. Messrs. W. Cuthush & Sons, sent a small collection of Onions, among which was Oscar, which was said to be a new and superior variety. Mr. Lumsden's collection of Potatoes (ten varieties) was a very good one, and contained excellent examples of Ashtop Fluke, Carter's Main Crop, Sutton's Red-skin Flour-ball, and other well-known varieties. A collection of Mr. Penn's new seedling varieties, was also shown, not for competition.

First-class Certificates were awarded to the following varieties:—

Chrysanthemum Duchess of Edinburgh (Veitch).—A beautiful rosy flower, intermediate between the Japanese and Anemone-centred types. It is quite distinct, and will soon become a favourite for decorative purposes.

Chrysanthemum The Cossack (Veitch).—A fine Japanese form of a rich bronze colour.

Chrysanthemum Gold Thread (Veitch).—A very distinct and beautiful flower of the Japanese type. The florets are very slender and wiry, being of a rich bronze colour, tipped with rich golden yellow.

Anthemium Williamsii (Williams).—A very pretty variegated plant, from the Cape of Good Hope, with green strap-shaped foliage, distinctly margined and striped with creamy-white or pale yellow.

Grape Mrs. Pearson (Pearson).—This is said to be a fine new variety, and in appearance resembles Royal Muscadine, but is larger in both bunch and berry.

Pear Pitmaston Duchess de Angoulême (Kemp).—A very fine variety of delicious flavour, well deserving a place in the most select collection of choice melting Pears.

Pear Lucy Grieve (Grieve).—A fine variety, ripe in October, and well worth culture as a richly-flavoured variety, juicy and delicious in every way. It is of English origin, having been raised at Cufford.

NOTES AND QUESTIONS.

[The following notes and questions came to hand or were answered too late for insertion in their several departments.]

Dacrydium Franklini.—This graceful New Zealand Conifer, long ago stated by Mr. McNab, in *THE GARDEN*, to be hardy, stood out the past winter at Glasnevin without injury, and is now in perfect vigour there.—V.

Duke of Edinburgh Rose.—This Rose is in charming condition this month; even as far north as the confines of the Low Peak it is flowering brilliantly at this date, distancing, in that respect, all competitors.—WILLIAM HEDSON, *Chase Cliffe, Derby*.

Cut Flowers not Preserved by Sal-ammonia.—I have placed flowers in sal-ammonia and water in the proportion of five grains to a pint and a-half of water, and the result is they have not kept any better in this mixture than other blooms placed at the same time in cold spring water.—A. HASSARD.

The Winter-flowering Clematis.—The pretty and curious *Clematis cirrhosa*, figured at p. 425, is now opening its solid-looking pale white buds at Glasnevin, and promises to be full of bloom, though the specimen is an old and almost worn-out one. It is a valuable plant for walls, bowers, root-work, large rock-work, sunny banks, and hedges in mild districts.—VICTOR.

Sarracenia purpurea at Glasnevin.—This plant, which has now stood a good many winters in the bog at Glasnevin, flowered freely during the past summer. The American Pitcher Plant has thus been proved by Dr. Moore to be as hardy in an Irish, as in a New Jersey, bog. It can, in fact, be easily grown in any part of England or Ireland.

Darlingtonia californica.—Of the many plants of *Darlingtonia* brought to this country of recent years, few seem to have lived, and the only really good example of this plant in a cultivated state we have seen is with Dr. Moore, of Glasnevin, where there is a plant of it in vigorous health, one of its pitchers being 15 inches long.

Abelia triflora.—This lovely and sweetly-scented plant is quite hardy at Glasnevin, its last flowers have just now faded after having been in bloom several months. It forms a well-shaped free-growing shrub, about 10 feet high. It may have been noticed as a striking wall-shrub at Kew, but it is even finer seen growing in the shrubbery, as in the Dublin Garden. The graceful *Abelia floribunda* is also quite hardy at Glasnevin against the greenhouse walls.

The Paris Red Flageolet Dwarf French Bean.—This is nothing more or less than the variety that has been placed before the public as Canadian Wonder; but, under whatever name it is held, it is really good; being equal in quality to any French Bean in existence, an immense cropper, and fit to send to table in a larger state than others. The weight of crop it produces is unequalled. It is a variety that ought to be universally grown, and cannot fail to give satisfaction in quality, appearance, and profusion of crop. For market it will become, as it gets better known, a general favourite.—T. BAINES.

Cannell's System of Heating.—It may not be out of place, perhaps, to state that we have lately adopted this system of heating one of the Vineries here. It consists in making the water travel along the two bottom pipes first, and then return to the boiler by the top ones, thereby making the return the flow. I can positively assert that, in our case, less firing is required than under the ordinary method, and that the water returns to the boiler in a hotter state, thus increasing the amount of heat to nearly double that which we had before we made this alteration.—H. STUBBIE, *Eltington Park*.

Pansy Miss Maitland.—Allow me to assure your correspondent "J. M." that I am not dissatisfied with this white bedding Pansy without good reason. My stock of it came direct from the firm who first sent it out, and I found that during the past spring and summer nearly one-half of the plants produced blooms very much discoloured with purple, which, of course, is a serious drawback in a white self-coloured Pansy. At Chiswick, this summer, four plants of it were grown, and two of these had discoloured blooms all the season. The plant has a good dwarf habit, and if its flowers were constant it would, undoubtedly, prove a capital white bedder.—A. D.

A Monstrous Liliun auratum.—Monstrous forms of the common Japan Lily (*L. speciosum*) are well known, as they have become so fixed that bulbs producing monstrous stems are offered for sale. We (*American Agriculturist*), however, never saw a monstrous Gold-banded Lily (*L. auratum*) until Messrs. Thorburn & Co. recently sent us a specimen. In this, as in the others, the stem is several inches broad, and flattened, as if what should be several stems were solider together, the upper portion being clothed with flowers as closely as they can be packed. This stem has been estimated to produce considerably over a hundred medium-sized blooms, and it is altogether one of the most wonderful specimens of floral abundance that we have seen.

Christie's Self-protecting Broccoli.—By a clerical error (see p. 437) I am made to say that I obtained seeds of this from Hull. What I did say was that the stock of it had passed into the hands of Mr. Dixon, of Hull. I was one of the few entrusted with the proving of this Broccoli for the last two seasons, and I wrote respecting it as I found it. It was sent to one of the Royal Horticultural Society's meetings, but, unfortunately, arrived too late; the Rev. C. Whichcote, to whom Mr. Christie is gardener, has letters from the committee regretting the mishap, and speaking of the Broccoli in favourable terms, and I must repeat that it is the finest Broccoli I ever saw or tasted, growing from 6 to 13 inches in diameter, and withstanding our hardest winters to all appearance.—R. NISBET, *Awarby Park, Fellingham*.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

FORCING HARDY PLANTS FOR WINTER FLOWERING.

ALL those perennials which, in the open air, bloom early in spring, are suitable subjects for forcing, and to the greater number of these the following cultural remarks are applicable. In spring, after they have flowered in the open air, the specimens intended for forcing should be potted, with good balls, in open loamy soil, or in a mixture of sandy loam and leaf mould, or heath soil, and plunged, during the following summer, in an open position. Here they should be watered abundantly, but no liquid manure should be given. At the approach of autumn, those plants whose leaves have withered should receive no more water. In rainy weather the pots should be laid on their sides, and after they have endured a little frost, the plants should be removed into a cool frame. Those kinds whose leaves have not withered, such as *Saxifraga*, *Vinca*, &c., should be watered in autumn, but only moderately, and those kinds which, in autumn, have begun to form flower-buds, and even flowers, as, for example, the sweet-scented double Violets, should be watered at that season whenever the soil is dry. With few exceptions perennials intended for winter flowering should be brought into bloom in a temperature not exceeding 45° to 50° Fahr., in a frame, pit, or low greenhouse. When the flowers begin to appear, it will be of service to the greater number of these plants to give them a watering with liquid manure once or twice. All perennials may be forced several years in succession. After forcing, they should be placed out-of-doors in spring, and treated during the summer as in the year before. In the following enumeration no allusion is made to kinds like the already popular Lily of the Valley.

Perennials for Winter Forcing.

Adonis vernalis.—In December this plant should be placed in a cool frame; when the new growth commences the plants should be set in a pit, in a temperature of from 45° to 50° Fahr., where they will come into bloom; no liquid manure should be given. The stems grow about 9 inches high, and the flowers are of a brilliant golden-yellow.

Anemone nemorosa fl. pl. and **A. ranunculoides.**—Two of the earliest spring flowers of our woods, the first with white, and the second with yellow, flowers. They require the same treatment as *Adonis vernalis*. Still finer is *A. apennina*, which should be potted in a mixture of heath soil and loam; and, treated like the preceding, when it will come into flower in about fourteen days after the *A. nemorosa*.

Aquilegia glandulosa and **A. vulgaris.**—Of the numerous species of *Aquilegia* these two are the best for forcing; the first is a native of the mountains of Siberia. It has produced many varieties, of which the form known as *A. jucunda*, with white petals and handsome sky blue sepals, is the finest. Of *A. vulgaris*, whose varieties in form and colour are very numerous, the double-flowered kinds are to be preferred for forcing. The fine variety of *A. glandulosa*, which is known as *A. g. jucunda*, should not be placed in much heat, as it cannot bear a high temperature, even in the early stages of its growth.

Caltha palustris fl. pl.—Only the double-flowered variety of this well-known plant, which grows in boggy ground, and has glistening deep yellow flowers, is to be recommended for forcing. It should be treated in the same way as *Adonis vernalis*, only that it should have loamy soil mixed with peat-soil; it should not be allowed to become very dry in autumn, and when blooming, and preparing to bloom, the pot should be set in a saucer so that the ball may be kept quite moist.

Dielytra spectabilis.—One of the handsomest perennials from northern China, producing, in great abundance, its peculiar, large, pendant, heart-shaped, and flatly-compressed flowers on bushy stems, from 1½ to 3½ feet high. Strong specimens should be selected for forcing, and potted in pretty large pots.

Epimedium rubrum.—A pretty dwarf plant from Japan, with flower-stems scarcely a foot long, and handsome red and

white flowers. It is forced in the same way as the *Anemones*. In addition to this finest of the species for forcing, we also recommend for that purpose *E. macranthum*, which has delicate white flowers; *E. Musseianum*, *E. pinnatum*, with yellow flowers; and *E. violaceum*, which has pale violet flowers. None of these should be placed in great heat, but gently pushed on in a frame or pit, so as to bloom about the beginning of March.

Helleborus caucasicus var. colchicus and **guttatus.**—Of the numerous Christmas Roses, these two are the best for winter-flowering. The first has brownish-red, and the second white, flowers tipped with red. The common Christmas Rose (*H. niger*), which is a native of southern Europe, and has large creamy flowers, may also be used, and particularly its large variety *maximus*. Though these bloom well out of doors in some districts, it is, in all cases, better to have good specimens of them in pots.

Hemerocallis Middendorffii.—A native of eastern Asia, with closely-crowded golden-yellow Lily-like flowers; treatment, the same as for *Aquilegia*. The other species of *Hemerocallis* are unsuitable for forcing.

Hepatica triloba, with its single and double white, blue, and carmine-flowered varieties, and *H. angulosa*, should be planted in a mixture of equal parts of leaf mould or heath soil and loam. The white-flowered variety of *H. triloba* and also *H. angulosa* are the only ones which will bear a little more heat than the others, and they may be brought into bloom by the middle of January. Late in autumn they should not be kept too dry, and should not be exposed to severe frost, otherwise their leaves will be spoilt.

Hoteia japonica.—A pretty dwarf plant about a foot high, with much-divided leaves, and handsome panicles of delicate white flowers. It is forced in the same way as the *Dielytras*, and can be brought into bloom by Christmas or the beginning of the new year, and continuously.

Iris florentina, **I. flavescens**, **I. pumila**, **I. Sambucina.**—All these can be forced into early bloom under the same treatment as that given for *Aquilegia*. *Iris pumila* may be brought into flower in January. The other kinds will flower in April, if grown in a warm pit.

Omphalodes verna.—In autumn the plants should be placed in a frame sheltered from frost, and soon afterwards removed to a temperate forcing pit, where they will unfold their beautiful sky blue flowers in the middle of December.

Orobis vernus.—Should be placed, in December, in a cool frame free from frost, and in January may be removed to a warm pit, where the blue and red flowers will appear in February.

Pæonia albiflora fl. pl., **P. officinalis fl. pl.**, **P. tenuifolia fl. pl.**—The pretty herbaceous Pæonies with double flowers, serve both as ornaments for the garden and for blooming indoors in April. About New Year's Day they should be placed in a temperature of from 40° to 50° Fahr. *P. tenuifolia* comes earliest into bloom, and does not require a large pot. It is, therefore, most to be recommended. A light watering with liquid manure should be given during flowering time.

Polygonatum vulgare (Solomon's Seal).—Its handsome foliage, on stems nearly 2 feet long, and its white pendent flowers, give this plant a very attractive appearance. It prefers a mixture of half leaf mould and half loam and sand, and blooms in April under the same treatment as has been given for *Aquilegia*.

Primula cortusoides.—A native of Siberia, with lilac flowers, *P. farinosa*, which grows in moist places on the hills of northern Europe, and on the Alps, and has rose-coloured flowers, and the underside of its leaves covered with a white mealy powder, and *P. viscosa*, a native of the Alps with deep red flowers, are to be recommended above all other species for flowering in March and April. In January they should be placed near the glass in a temperate forcing house, in a rich mixture of heath soil or leaf mould and loam.

Trollius asiaticus, **T. altaicus**, **T. europæus.**—The first two kinds are only found in Siberia, and have glistening orange-coloured flowers. The last is distributed over the whole of Europe and Siberia, and has sulphur-yellow flowers. Treatment the same as for *Aquilegia*. M.

NOTES OF THE WEEK.

— DR. WOODMAN writes to us to say that in Lacombe Pince & Co.'s nursery at Exeter there is a plant of *Lapageria rosea* which has grown on an outer wall there for many years, and which is now in full bloom, bearing about 100 splendid flowers of unusually good substance. When the frost is very severe, it is given a little protection, but otherwise it has to take care of itself.

— A PLANT of *Davallia Mooreana*, at Drumlanrig, has produced and is at present furnished with 118 fully-developed fronds, which have a spread of 8½ feet. This unique specimen is grown in a 22-inch pot, and is probably the largest in Europe. It is one of the best and most beautiful of all the *Davallias*.

— MR. ATKINS, of Painswick, has brought under our notice some slate labels which he has used in his garden for several years, and prefers them to any others. In shape they are like the common wooden label. They are painted white, and, whilst the paint is wet, then marked with a black lead pencil or a pointed implement of any kind. The manufacturers are Messrs. Sessions and Sons, of Gloucester. Mr. Barr, we understand, intends trying them in his grounds at Tooting.

— WE have received from Messrs. Neumann & Co., of Great Tower Street, a sample of the new Balata gum, to which reference was made last week (see p. 451). This gum, however, being non-elastic, cannot be used in place of indiarubber, but for articles generally made of the purest gutta percha it will answer perfectly. It, however, requires totally different treatment from either india-rubber or gutta percha.

— A NEW temperature indicator has just been brought under our notice by Mr. Clement Marsh, Chetwynd House, Wolstanton, Stoke-on-Trent. One form of the instrument, applied to an ordinary thermometer, seems well suited for plant structures of all kinds; it is so contrived as to operate on an alarm bell at a minimum or maximum temperature. The bell-ringing continuously arouses the attention of the gardener, and at once proves to him, that the temperature is either too high or too low. The bell can be fixed anywhere, and at any distance from the instrument; it is a mere question of length of wire. As a fire detector it promises to be invaluable.

— WE have received flowers, in beautiful condition, of the following plants, all of which are hardy and naturalised in Mr. Ellacombe's garden at Bitton, viz., *Solanum jasminoides*, a beautiful white-flowered climber, with fresh green foliage and Jasmine-like flowers; *Iberis semperflorans*, a dwarf fleshy-leaved Crucifer, much prized on the Continent as a pot plant on account of its delicately-fragrant white flowers, which are borne in dense clusters; the true Jalap plant (*Exogonium Purga*), with rich purple *Convolvulus*-like blossoms; *Gaura Lindheimeri*, a tall whitish-flowered herbaceous plant, much grown in French gardens, and recently flowering on the rock-work at Kew; *Abutilon vexillarium*, a well known half hardy shrub, which bears a profusion of bright orange-scarlet and yellow flowers. Associated with these were also *Bryonia sanguinea*; *Saxifraga Fortunei*, a useful kind with spikes of showy white flowers; the charming winter-blooming *Clomatis cirrhosa* (figured at p. 425), a useful species which bears large drooping greenish-white bell-shaped flowers in profusion; *Allium suaveolens*, with Thrift-like heads of creamy-white flowers; and *Erica codonodes*, a dwarf and very pretty winter-flowering Heath—all bright and well coloured for this season of the year.

— MR. G. SHAW LEFEVRE, in a letter to the *Times* the other day, with reference to the decision of the Master of the Rolls last week in the Epping Forest case declaring enclosures since 1851 to the extent of 3,200 acres to be illegal, calls attention, among other cases of disputed common rights, to that of Hampstead Heath, and points out that the purchase of this property by the Metropolitan Board of Works for £50,000 was not only unwise but unnecessary; for, had the suit then pending with the lord of the manor been suffered to take its course, there can be no doubt now as to the result being in favour of the commoners. It is on every account to be regretted that a compromise was effected before the legal points involved in the case were brought to an issue; for by some process many of the most picturesque and beautiful portions of the Heath not included in the bargain with the Board of Works were enclosed at the time of the purchase, and are now lost to the public, who, there is every reason to believe, after the decision in the Epping case, might otherwise have had the enjoyment of them for ever. The little village greens, also contiguous to the Heath, which from time immemorial were the favourite playgrounds of the poor, have, in like manner, within the last three or four years, been appropriated for private uses, and it is a question well worth consideration, whether some attempt might not be made in this and other similar instances to test the legality of the

enclosures, and to restore to the public at least such lands as have not yet been built upon, and which may appear to have been improperly taken from them.

— THE Thames Embankment is gradually becoming the handsomest Boulevard in Europe. When its trees and gardens have had time to develop themselves, the embankment will be far finer than anything of the kind in Paris or elsewhere.

— A DIRECTORY OF BOTANISTS, comprising lists of gardens and directors of gardens, and professors and curators, of the whole world, has been published under the superintendence of Professor Morren, at Liège. This is no new undertaking, but it is as yet insufficiently known, and is so peculiarly useful that we advise all who are likely to need to consult such a work to make note of it at once. It contains the names and addresses of about 750 botanists.

— THE report of the Potato Disease Committee of the Royal Agricultural Society has been recently published. It will be recollected that three years ago Earl Cathcart offered a prize of £100 for essays on the prevention of the disease. Although no fresh practical information was elicited, and it may, perhaps, be said no direct good came from this well-meant offer, the Society took the subject up and offered prizes for Potatoes reputed to be proof against disease. Two prizes were offered for the commencement of this year, for Potatoes of varieties already known, and two are to be awarded five years hence for varieties that may be produced by cultivation before that period. Six different varieties were sent in, one ton (twenty bags of one cwt.) of each. The Society arranged to have these practically tested. Twelve stations in England, four in Scotland, and four in Ireland were selected, and 1 cwt. of each variety sent for planting, of these so-called disease-proof Potatoes. During the summer the botanic referee of the society visited all the localities, and in all cases disease was found. Much valuable information is likely to arise from the statistics that have been collected, for although it seems that no indication is given of how the disease can be prevented, yet, under certain conditions, principally influenced by moisture, its effect is but small.

— GENERAL CHANZY, this past season, issued a circular to the generals of division and prefects in Algeria, directing them, in dealing with grasshoppers, to adopt the method which has been successfully employed in Cyprus. This comprises systematic seeking and destroying of the grasshoppers' eggs, and also attacking the crickets on the march. It seems that before becoming full-blown grasshoppers the crickets, about a month after they are hatched, begin to march, and this they do in large, compact masses for a period averaging some twenty-seven days, during which they never swerve from the line of route once adopted. The people of Cyprus take a band of silk, from 65 to 70 centimetres high and 100 metres long, and this they tie vertically to poles firmly fixed in the ground, the upper part being waxed or bordered with oil silk to a width of about 10 centimetres, and the earth so heaped up under it as to leave no crevice between the silk and the ground. A second band is then set up, so as to form a sort of gallery of gradually diminishing width, being at the month somewhat wider than the column of crickets, but only 5 metres wide at the other end, where is a trench 5 metres long, one and a half wide, and one deep. This forms the trap or "system," several of which, 100 metres long, can be placed end to end and transported to any point threatened by the invaders. All that has to be done is to wait till the column of crickets has reached the trench. Then it is covered in with earth, and nothing more is seen of the crickets.

— M. CORENWINDER has contributed to the *Société des Sciences*, of Lille, an exhaustive series of observations on the processes of respiration and nutrition in plants. He supports M. Claude Bernard's view, that the process ordinarily known as the respiration of plants—the decomposition of the carbonic acid of the atmosphere—is really a process of digestion, and that simultaneously with this, plants carry on, by day as well by night, a true process of respiration, similar in all respects to that performed by animals, consisting in an oxidation of the carbonaceous matters of their tissues. By a very careful series of analyses, performed mainly on the Lilac and Maple, M. Corenwinder determined that the proportion of nitrogenous matter in the leaves gradually and progressively diminishes from the time that they emerge from the bud till their fall: the proportion of carbonaceous matter increases very rapidly during April and May, and then remains nearly stationary till October; while that of incombustible substance increases during the whole period of vegetation. He distinguishes, therefore, two periods in the vegetative season of the plant—the first period, when nitrogenous constituents predominate, is that during which respiration is the most active; the second, when the proportion of carbonaceous substance is relatively larger, is the period when respiration is comparatively feeble, the carbonic acid evolved being again almost entirely taken up by the chlorophyll, decomposed, and the carbon fixed in the true process of digestion.

RAISING NEW KINDS OF PLANTS.

THE artificial fertilisation of plants, by means of which so many new and splendid varieties have been obtained, is an art which was but guessed at by the scientific men of the last century, and almost totally unknown to the immediate predecessors of those occupied in the various branches of horticulture. Even at the present day its principles are but imperfectly known and still more imperfectly practised; and yet such brilliant results have been obtained by comparatively rude knowledge and practice as ought to incite to more careful and accurate study and manipulation, which cannot fail to lead to rapid progress in this interesting and important branch of horticultural art—an art which is the most potent lever we possess for modifying and occasionally entirely changing the forms and general aspects of vegetable life. From the most minute herb to the stately Elm, Pine, or Oak, man is enabled, by its means, to produce an infinite variety of new forms, as to general habit of growth, foliage, inflorescence, and fruit; the new varieties so produced, at the bidding of a skilful operator, being frequently far superior to the former types, in so much that the original species of several of our most favourite garden flowers have actually disappeared before the invasion of a host of superior and far more splendid varieties obtained by the means of artificial fecundation. To the agriculturist seeking to improve his cereals and his root crops, artificial fecundation of suitably-selected species will, with skill and perseverance, inevitably crown his aspirations with brilliant success; while the commercial horticulturist, and the amateur who loves his garden and his plants for themselves, should vigorously pursue the practice of this new and wonderful art, which touches the highest and most mysterious pinnacles of vegetable physiology as with the wand of a necromancer—so great and striking are the metamorphoses which may be wrought by its means. It was by this art that M. Sonchet, of Fontainebleau, produced all those dazzling varieties of Gladioli; and that M. Gerain, of Rheims, succeeded in raising his magnificent series of Petunias with both double and single flowers, which have made his name famous in the annals of floriculture; and Messrs. Caulier, of Vailly, produced their remarkable series of Zinnias in the same way. What has become of the old forms of Geranium, Coleus, Gloxinia, and Caladium? They have disappeared to make way for the magnificent array of their respective kinds produced by the magic of artificial fecundation. The results obtained by English experimentalists have been still more striking, as evidenced by the Clematis culture of Mr. Jackman, and the striking amelioration of the higher classes of fruits by Mr. Rivers.

Fertilising by artificial means is like the opening of a mine of some precious and previously unknown product, which is inexhaustible, but of which only a few straggling veins have as yet been laid bare. How much pleasure and unalloyed gratification and satisfaction may be derived from the practice of an exquisite art, by means of which we may change the face of Nature itself, making it at once more beautiful and more useful to our race; by the production of new and more robust developments of our grandest forest trees, of nobler forms among our fruit trees, bearing more abundantly, richer and more delicious fruit, and of forms of culinary vegetables of such unproved growth and succulence that the present varieties will drop out of cultivation, and be no more heard of in the annals of horticulture, except as “pre-historic” developments, as it were destined to be eventually forgotten in the annals of the art of gardening.

The results of artificial fertilisation in England and Belgium appear so remarkable to those who thoughtfully consider the powers of this astonishing art, that they have been deemed, by M. Lambin, “nothing less than prodigious.” The best works that have been published on this deeply interesting subject should be carefully read and studied by both amateurs and commercial practitioners in horticultural pursuits. M. Henri Lecoq’s work, “De la fécondation naturelle et artificielle des végétaux, et de l’hybridation,” is full of instructive matter, and imparts in an agreeable and practical form almost all that is at present known on the subject, accompanied by careful descriptions of the best methods of operating. Furnished with the knowledge thus acquired, the manipulator may fearlessly engage in the enterprise of raising new varieties in every class of the vegetable kingdom; and need not be troubled with doubts that Nature may get tired by his insatiate demands upon her ever prolific powers, for they are inexhaustible.

There are two distinct kinds of vegetable fertilisation—the natural and the artificial. In the natural one, the pollen of the male flower falls upon, and fertilises without extraneous aid, the reproductive portions of the female flower. The chief function of the general form of a flower appears to be the protection of the delicate structures immediately connected with re-production, and to place them in a suitable position to receive the necessary influences of the atmosphere and the particles of the fertilising pollen.

The ordinary floral envelope of the reproductive apparatus consists

of the calyx and the corolla. The corolla is composed of the petals, which are generally the coloured portion of the flower, and serve as the enclosure of the stamens. Where the petals are separate, as in a Rose or Daisy, the flower is termed polypetalous. Where they are more or less attached to each other, or are without any separation at all, as in the Convolvulus, they are termed monopetalous. The base of the petal or petals is protected by the calyx, or cup, which partakes of the nature of foliage, and is generally green; its divisions being termed sepals. Its function is to protect the base of the stamens, and the ovary or seed vessel. The reproductive organs consist of the pistil or female organ, and the stamens or male organs. The pistil is placed prominently in the centre of the flower, and consists of the ovary, the style, and the stigma. The ovary at the base of the pistil contains the rudiments of seeds, which are termed ovules. The style is surmounted by the stigma, which varies in its aspect and form, but is nearly always moist with a viscous secretion, to which any particles of pollen falling upon it adhere and are dissolved. The stamens, or male organs, consist of the anthers, covered with pollen, and the filaments, upon the point of which they are raised. The pollen, or fertilising powder, examined through a microscope, appears to consist of a mass of small vesicles or granules, of which the form and colour vary with every genus of plants, and often with different species of the same genus. Each granule contains a mucilaginous fluid, and this fluid is conducted by means of the stigma and style to the ovary.

When both the pistil and fertilising stamens exist in the same flower, it is called hermaphrodite, as combining both sexes; as in Peach-flower, the Apple blossom, and the Lily. When the pistil and stamens are not found in the same flower, but are in separate flowers on the same branch, the plant is called monœcious, of which the Walnut, the Melon, and the Mulberry are examples. When the male and female flowers are found on different plants, the plant is called dioecious, as in the case of the flowers of the common Hemp and Spinach, and in Palms; finally, plants are termed polygamous, which have both male and female and also hermaphrodite flowers, examples of which are the Pimpernel, the Gleditschia and others. In order that the fecundation may take effect, it is necessary that the pollen of the anthers should come into contact with the stigma. If the stigma and stamens exist in the same flower, the anthers are generally so placed as to be very near to the stigma, so that the fructifying particles furnished by the anther may fall upon the stigma, or be carried to it by insects, or other means. In aquatic plants, especially those which flower beneath the surface, special arrangements exist for the prevention of injury to the pollen by contact with the water, and in apetalous kinds the pollen is superseded by a fluid. The various means (remarks M. Lecoq) that are resorted to by Nature to ensure the successful fertilisation of plants, commends our fervent admiration, and those means are never failing, except when interrupted by extraordinary accidents. In the Rafflesias, of which the sexes are almost invariably situated at considerable distances from each other, the viscous nature of the pollen does not permit the action of the wind to convey it to the female flowers, which are fertilised by unconscious insects, who, deceived by the cadaverous odour of these plants, descend into the depths of the corolla, and, finding their mistake take flight with portions of the viscous matter attached to their legs, wings, or proboscis, and, deceived a second time, carry it with them into the corolla of another flower, probably a female, which is thus fertilised by adventitious aid. Often, too, insects have been the unconscious fertilisers of flowers not requiring foreign assistance. In such cases, carrying the pollen of one related species to another, and being the cause of the appearance of new hybrids, from time to time, in our gardens and orchards, long before human discovery, and the ingenuity of man, had reduced artificial fertilisation to a regular science; which, though yet in its infancy, has already led to extremely interesting, and, indeed, magnificent results. The fertilisation of plants by foreign agency, either accidental or scientific, has however, its limits. It can only take place between plants of the same group, and is generally confined to such as stand in near botanical relationship to each other; which renders it necessary to say a few words on species and varieties. A species is a botanical unity—above it is the family, below it are the varieties—as for example, Wheat is a species, but red Wheat, and white Wheat, are only varieties of the one typical species. The Red Currant, the Black Currant, the Thorny Currant, or Gooseberry, are distinct species; varieties of each may occasionally appear producing larger or smaller, or more highly coloured fruit, but neither the Red or Black Currant will ever produce single fruited varieties; nor will the Gooseberry ever produce fruit in bunches like any of the species of Currants. It is hence seen that variations of species have their fixed limits. The object, therefore, of those who attempt the artificial fertilisation of the reproductive organs of the flowers of plants, must be concentrated upon the

improvement, and not the entire alteration of the general form and character of species. With these facts in view, improvements by selection necessarily becomes the only legitimate object of the hybridiser. He must take the pollen from only the finest plants—especially those furthest removed from their original wild state. It is in this way that a continuous progress in the perfecting of flowers and fruits will henceforward be kept up in flower, fruit, and vegetable culture; and also in the various kinds of plants which form the staple of field culture.

It now remains to set before the intending manipulator the best methods of performing the operation of artificial fertilisation, and the various precautions which must be carefully observed, in order to ensure success. In the first place, it is perhaps scarcely needful to tell the operator, that to hybridise a plant, it must be artificially fertilised by another of the same genus, as for example, a white Rose by a red or a yellow one. Before operation, great care should be taken to secure the pollen from well and perfectly developed anthers of the male plant, or it may be such as will not produce a successful result when it is sought to fertilise the female plant. In general, the hybrid partakes of the nature of both parents; though, in many cases, the influence of the female parent is the greater. The selection of the species to be artificially fertilised requires much care. For instance, when it is desired to obtain an improved fruit, it should be taken into consideration, whether it is an early or a late fruit, of its kind. If late, then it should be crossed with a plant which ripens its fruit about the same time; or, if an early sort is about to be dealt with, the fertilisation should be from some other early kind; and other qualities should be observed in a similarly scrupulous manner, especially in the matters of the saccharine, farinaceous, or aromatic properties of culinary vegetables, which it is sought to improve. It has been by carefully studying the kind of amelioration required, and the subjects most likely to impart it, as well as those most likely to receive it, that such magnificent results have been already attained in this country. Another principle has to be observed. So soon as a new and very desirable variety has been obtained, its influence should be utilised at once; as new varieties are much more easily obtained from it before it has acquired that individual stability which habit eventually establishes.

Double flowers may be accidentally obtained from seed, but the results of careful selection in the fertilisation of double or semi-double flowers, in order to produce varieties still more double, is much more satisfactory than waiting for such chance varieties as may arise from unconscious fertilisation by insects or other causes. In order to improve the progressive development of any new character by selection, M. Lecoq tells us that he has sometimes fertilised double varieties, selecting both parents from already very double varieties, and that the result was the production of several new hybrids, the flowers of which were so excessively double that the buds invariably burst, and a perfectly opened flower never occurred upon the plants, as is sometimes the case in new hybrid Carnations and Pæonies. But out of the same experiment several single-flowered varieties were also produced, as though by the selection of both parents, disposed to produce a vast number of superfluous petals in each flower, the tendency had become entirely neutralised, and the offspring had returned to the original single type. As regards the respective colours of the parents in hybridisation, it has been observed that the colour of the flowers of the female parent generally predominates over that of the male. If, therefore, it is sought to obtain a hybrid bearing flowers of darker colour than those of either of the parents, the tone of colour of the flowers of the female parent should be darker than those of the male. But if it is wished to lighten the tone of colour, then, in most instances it would be well to select a female parent bearing white flowers, or, at all events, flowers of a very light colour. Sometimes the attempt to deepen, or render lighter certain tones of colour by hybridisation results in the production of striped flowers, in which the colours of both parents are preserved intact in that form—as in Tulips, Belladonnas, and many other plants.

The preparation of the subjects to be operated on is very important. In the first place, these should be placed in the most favourable position possible for maturing their seed. Secondly, it is important that the possibility of contact with other pollen than that intended to produce the kind of fertilisation required should be guarded against. In hermaphrodite plants, the anthers must be removed as soon as the flowers open. In monœcious plants the male flowers must be removed as fast as they appear; and, in dioecious plants, the plant bearing male flowers must not be allowed to remain in the neighbourhood of the female plants. Thirdly, it is desirable, both in the collection of pollen and in the artificial fertilisation effected by its means, to select only terminal or principal flowers. Fourthly, when the blossoms of fruit trees are to be fertilised, it is desirable to place the branch bearing the flowers to be operated on beneath a bell-glass, upon a

thick layer of Moss, in order to protect the blossoms from any kind of accidental fecundation. Fifthly, in preparing culinary vegetables or cereals for artificial fecundation, the plants intended for the operation should be isolated, in the remote corner of a garden, or other situation where the pollen of allied kinds would be unlikely to reach them by the interposition of insects or other causes. Sixthly, suitable instruments, such as blunt-pointed scissors, sable brushes, &c., should be provided for the amputation of stamens and other purposes. M. Brassoul, cutler, Rue Gay-Lussac, Paris, has invented a neat little set of instruments for hybridising purposes, which are a great luxury; and all that could be desired; but ordinary scissors, pincers, and a sharp penknife, in the hands of a skilful operator, are sufficiently handy—"good workmen never quarrel with their tools." In most instances the excision of the stamens immediately after the expansion of the flower will be found sufficient precaution; but, in certain flowers, the fertilisation takes place previously to their expansion, and, in such cases, it becomes absolutely necessary to make a careful incision in the unopened bud before the opening of the corolla, and to extract the stamens before the dissemination of the pollen. This operation requires neatness and precision; but, with delicate handling, it may be performed with seldom varying success; care being taken not to crush the anthers in the least degree, and not even to throw them down carelessly near the plant, as insects might carry particles to the flower about to be hybridised.

The preservation of pollen about to be used in hybridisation, will require great care, if brought from a distance. It often happens that the pollen required to fertilise a plant cannot be procured exactly at the time desired; and, if it be necessary to keep it for some time without using, the following precautions may be observed: place the collected pollen in the hollow of a watch-glass, and let it remain exposed for a few hours (but not in the sun) till a portion of its moisture has evaporated; another watch-glass of the same size may then be placed over the one containing the pollen, and made airtight by the application of gum round the edges. As to the length of time during which it may be thus preserved, nothing precise is known, except that the pollen of some kinds of plants will keep much better than that of others. M. Haguin, of Liege, has fertilised Lilies with pollen that had been collected for more than forty-eight days—Azaleas, with pollen forty-two days old; while Camellias respond to the fertilisation of pollen that has been kept for sixty-five days. These periods are far exceeded by that of the retentive powers of the pollen of *Ceratostamia mexicana*, which after being preserved from 1866 to 1873, was successfully applied by M. Houlet, chief of the plant-houses of the Jardin des Plantes. Nevertheless, M. Bleu, well-known as the producer of a noble series of hybrid *Caladiums*, states his full conviction that the freshest pollen is the better. M. Haguin cuts the anthers he requires immediately on the opening of the flower, wraps them carefully in a pasted-up seed paper, and leaves them in a dry and warm situation for twenty-four hours. By that time the fecundating dust has fully ripened, and M. Haguin then envelopes it closely in thin sheet-lead, numbering and naming each kind, and placing them in a dry, but cold, situation, till required for use. M. Perrolet, reports from Guadalupe, that the male pollen of a Date Palm (which flowers three months before the female tree), was kept during the three months required without injury.

The application of pollen should be effected in the following manner. The morning is, in most plants, the period of the day in which the stigma is best prepared to receive it. With the first rays of the sun, therefore, the operation should be performed. The only exceptions are, where the plant to be fertilised is an evening or night flowerer, in nearly all of which fertilisation is rapidly effected immediately on the opening of the flower; therefore, care must be taken to seize quickly the favourable moment. Nothing is more simple and easy than the actual application of the pollen; a small quantity of the pollen taken up with a camel-hair or sable pencil and placed gently upon the crown of the stigma is all that is necessary; that done, the operation is completed. M. Olivier Gerain, of Rheims, moistens the pollen with a drop or so of water, which is painted on to the stigma in that state, with a small sable brush, and it is by that form of application that he has produced the fine strain of brilliantly-coloured *Petunias* for which his establishment is so well known. When the pollen is applied to the stigma it enters into immediate communication with the viscous liquid there secreted, and is thus conducted through the tissues of the stigma to the ovules, or embryo seed, which it fertilises. This connection is no sooner consummated than the beauty of the flower begins to fade, and the brilliant corolla withers and falls; all the energies of the neighbouring parts of the plant becoming concentrated upon the development of the fruit, or seed vessel, and its contents. The seed vessel has a double function to perform, that of nourishing the seeds during their growth and ripening, and also that of protecting them from external injury. W.

THE INDOOR GARDEN.

FRUIT OF STEPHANOTIS FLORIBUNDA.

This well-known and exceedingly ornamental climbing plant has, ever since its introduction from Madagascar, been a great favourite, and has formed one of the most graceful ornaments of our stoves. It is, however, very rarely that it has produced its fruit in Europe. M. Carrière, the well-informed editor of the *Revue Horticole*, believes that it has fruited for the first time in Europe, during the present season, in the garden of an amateur at Pentolise. In 1868, however, we saw a plant of it bearing fifteen fine fruit, each as large as a Jargonelle Pear, in Lord Berner's garden at Keythorpe, and it has now and then fruited elsewhere in this country. The flowers of the *Stephanotis* are great favourites with bouquet makers in Covent Garden. Their pure white colour and their elegant form seem to have rendered them specially desirable for floral decorative purposes at weddings; and as a chief feature in button-hole bouquets they have become indispensable, while in wreaths and massive hand-bouquets for such occasions they seem to have partially displaced Orange-blossoms themselves. Though so well-known as a cut flower, some of our readers may know little of the entire plant, and may be glad to learn, from our engraving, something of its appearance when in fruit.

ORCHIDS AT LORD LONDESBOROUGH'S.

THE fine collection of Orchids at Norbiton, well deserves especial notice for several reasons. Most practical Orchid growers will agree with us that the less Orchids are removed from the houses in which they are grown the better; and yet no collection of plants has travelled so much as that now under consideration. When the collection was grown at Grimston Park, near Tadcaster, especial arrangements were made, and a heated railway van was employed to bring plants from it in bloom to London. Nor were they thus shifted about merely for the gratification of their owner, as, at nearly every meeting of the Royal Horticultural Society then, as now, a group of plants from Lord Londesborough's collection was staged. In spite, however, of inevitable drawbacks to growth, consequent on such transitions, the collection still remains one of the finest in Europe. Cattleyas generally look well, and at the time of our visit a plant of *C. gigas* bore three fine flowers, one having been removed for artistic purposes. It is a robust and showy variety, but will not bear comparison with the true old *C. labiata*, which we have always considered, when well grown, to be the finest of all Cattleyas. Of the last named plant a noble specimen has borne three fine spikes, or, in all, fifteen flowers. These, for size, form, and richness of colouring, we have never seen surpassed. How gorgeously beautiful this plant is!—and yet how seldom do we see it grown. Imagine great broad petalled flowers, of the softest lilac, delicately frilled and crimped so as to represent the subtle colouring in at least a dozen different shades, and these again blended into other intermediate shades with inimitable softness and delicacy. It is, however, when we come to the great frilled open-throated lip that we are most astonished—what an array of royal purple, crimson, and cloth-of-gold barred with ruby, have we there! Ruskin, in one of his books, asks, what artist ever yet painted the delicate throat of a Foxglove bell? If this, then, is so difficult, how much more so must it be to represent the ever-varying tints of these protean Orchids? We now come to a group of Phalenopsids, in which a vigorous plant of *P. Lowii* is furnished with a great branched spike bearing thirteen

flowers. The spike is fully 18 inches in length, and the individual blossoms are 2 inches or more across. This is so handsome that even the queen of Orchids herself (*P. amabilis*) has to yield in point of beauty. The segments of the flowers are of a soft rosy-lilac, pearl-like in lustre, while the apex of the narrow lip is of the most brilliant amethyst-purple. Mr. Denning has been most successful with this plant, which is, as most practical Orchid growers are aware, one of the most difficult to cultivate in the whole group. Here, however, its leaves remind one of those of *P. amabilis*, except that they are more sharply pointed, and are freckled with the characteristic purple dots. Side by side with the last named hung two plants of the rare *P. intermedia* Portei—perhaps the rarest, and certainly one of the most beautiful, of all cultivated Orchids. It is supposed to be either a seedling variety or natural hybrid, and only a solitary plant has as yet been discovered in its native habitat—the Philippines—while from this have been raised the plants now in cultivation, and which might be counted on the fingers of one hand.

The largest plant here is unique, and is as vigorous in appearance as a strong plant of *P. amabilis*, to which it certainly bears some resemblance in habit. It is now bearing a strong flower-spike; but the blossoms will not be open for some weeks yet to come. Some strong masses of *Epidendrum bicornutum* are making a vigorous growth, suspended in baskets near the glass, and a plant of the pretty little *Angraecum bilobum* is flowering freely. The singular "Cockatoo plant" (*Angraecum Ellisii*) has just flowered, and deserves mention as a souvenir of the late Mr. Ellis, to whom we are indebted for several showy *Angraecums*, and also for the "Lattice Leaf" plant (*Ouvirandra*). The Cockatoo plant is distinct in habit, and in its growth somewhat resembles a *Renanthera*. A plant of the best variety of *A. eburneum* is growing well, and is now throwing up a stout spike; while a fine plant of *Coelegyne Rhodeana*, with fluted pseudo bulbs and bright green leaves, is a mass of pale brown-spotted flowers. *Dendrobium Falconeri* is making plump and vigorous growth. This is one of the finest of all *Dendrobes* when in bloom; but, unfortunately, that is seldom the case. A plant of the lovely golden-flowered *D. chrysotis* (*D. Hookerianum* of the Bot. Mag.) has the finest growths of any specimen we have yet seen, these being in some cases fully 6 feet in length. This specimen is even finer than the one sold at Mr. Sam Mendel's sale; and, when strong and healthy, flowers very freely. A splendid specimen of the chaste *Cymbidium eburneum*

Fruit of *Stephanotis floribunda*.

is now showing flower, and is in perfect health. This is one of the finest specimens in cultivation, and ranks with that in Mr. Russell's collection at Falkirk or Mr. Dodgeson's at Blackburn. Another pretty species, *C. Mastersii*, although less effective, is still well worth a place in the most select collection; here it is bearing five or six gracefully-curved spikes of milk-white flowers with pale pea-green bracts. Here, too, are two of the finest specimens of *Dendrobium Kingianum* in Europe, both in robust health and growing freely. This is a pretty rosy-purple-flowered Australian species, which, apart from its rarity, well deserves culture as a free-flowering and beautiful plant. Another rare *Dendrobe* (*D. Lowii*) is represented here by two specimens, both fresh and healthy. This belongs to the nigro-hirsute or black-haired section, and produces golden-yellow flowers with a peculiarly hairy lip. A plant of *Thunia alba* had just flowered, but Mr. Denning informed us that it is more beautiful than some of the paler varieties of *T. Bensoniae*. It had made a vigorous growth, the stems being fully a yard in length, and proportionate in thickness. We also noticed strong healthy plants of *Dendrobium nodatum* and the delicate green-flowered *Dendrochilum filiforme*, the spikes of

which resemble, to some extent, delicate filigree jewelry. Passing into one of the cooler houses, we came upon *Odontoglossum* and *Masdevallias*, literally revelling in the fresh airy atmosphere and genial humidity so essential to the growth of these plants. Here, for the first time, we had the pleasure of seeing the pure white variety of Roez's *Odontoglossum*, a decided acquisition, and one which will be thought by many to be more beautiful than the purple-blotched variety. The flower is perfect in shape, having snow-white sepals, petals, and lip, with the exception of a stain of clear lemon-yellow at the base of the latter; this plant will form a worthy companion to the white *Lycaste*. The *Masdevallias* were in fine condition, about half-a-dozen species being in flower at the time of our visit. *M. Veitchii* was, of course, one of the best, possessing, as it does, so rich a variety of bright colours. *M. ignea* is another brilliant little gem, the flowers of which glow like red-hot iron, especially when contrasted, as in this case, with the cool snowy flowers of *M. towarensis*, the inimitable texture of which can be likened to nothing so much as that of a snow-flake. *M. peristeria* has curious sombre-looking greenish flowers, mottled with dull brown within, like some of the *Stapelias*, but the lip is very beautiful when examined closely, being hinged almost as delicately as that of a *Bolbophyllum*, and set with dense purple papillae. *M. Estradiae* is another little gem, with rich dark purple flowers. In habit it somewhat resembles *M. coccinea*, the leaves being only an inch or two in length, and of perfect outline—so much so that the plant is always interesting, even when out of flower, which must, indeed, be seldom, as the plant now under notice was furnished with a plentiful supply of new buds, and some of its former flowers were only just on the verge of decay. We hope yet to see great pans of *Masdevallias* at our floral exhibitions with from twenty to fifty flowers on each. Imagine *M. Veitchii* with fifty flowers all open at once. Why even the scarlet *Anthurium* would look of a dull brick-red compared with it. We have already seen the chaste little *M. towarensis* with thirty-six flowers on a plant scarcely a foot in diameter, and we feel assured that this will be much exceeded in time. Side by side with the *Masdevallias* were two or three plants of *Odontoglossum vexillarium* now making vigorous growth; Mr. Denning told us that one of these plants had borne a magnificent arched spike of richly-coloured flowers this season. Some plants of *Cypripedium* *insigne* were blooming freely, but, in point of beauty, these were far surpassed by a vigorous plant of the true *C. insigne* Maulei, which, as here seen, is one of the best of all the *Lady's-slippers*. It is distinct from the common variety in habit, the flowers being larger in size, and the broad upper standard or sepal is of a pure white half its length, and blotched with clear light purple, not greenish-white, blotched with dull brown as in the common form. This is a plant which should be in every collection of cool-house Orchids; but, like many other good things, it is but seldom met with in true character. To buy it in bloom is the surest way to obtain it true to name, and even if 50 per cent. more is paid in consequence, one has the consolation of knowing that future disappointment is impossible. Another really good and showy plant well worth general cultivation by all amateur Orchid growers is *Epidendrum Catillus* (*E. Imperator* of Linden), one of the tall-growing kinds, which bears large terminal clusters of reddish-crimson flowers, such as might almost be mistaken for *Ixora* blooms were it not for the magical soft lilac and white of the arrow-headed or jagged lip. This plant possesses the good property of blooming for ten or twelve months in succession, and then, when one cluster of flowers is past its best, a new one makes its appearance a little lower down the spike, just as often occurs in *Phalenopsis*. *Epidendrums* are not general favourites, but this may be considered as the gem of the group or section to which it belongs. Some plants of *E. vitellinum* majus in the same house are making vigorous growth and promise well for future display.

The north side of a span-roofed house we found devoted to the cooler growing Orchids and *Odontoglossums*, being divided from the southern half by a glass partition. In order to afford the necessary shade, some thick tiffany or other coarse fabric is strained over the glass, and is found to answer admirably. Here we found dozens of *Odontoglossum Alexandrae* and *O. Pescatorei*, most of them throwing up flower-spikes in all directions. One variety had the most perfectly formed spike we have ever seen, its pearly flowers being arranged in the most graceful natural wreath imaginable, and here and there suffused with delicate rosy-lilac, the base of the fringed lip being suffused with soft golden-yellow. A fine plant of *O. cristatum* bore six fine spikes which drooped around the pot on all sides, and a very fine variety of *O. Hallii* was furnished with four good spikes. The lion of the collection, however, was a splendid specimen of the last named plant, on which we counted seventeen flower-spikes, many of them branched. This was not at its best, but when in full flower will be a sight worth seeing. A plant of *O. coronarium* bore a stout erect spike of brilliantly-tinted flowers, which, in both form

and colouring, are quite distinct from any other *Odontoglossum* which we have yet seen. The colour of the rounded segments is a bright reddish-brown, shiny as if varnished, the lip being golden-yellow, blotched with brown, and barred with deep rich purple. This plant is not unfrequently met with in collections, but, as a rule, it flowers very rarely; still, Mr. Denning has succeeded in blooming it every season since 1870, when it flowered, for the first time, we believe, in this country, under his management at Grimston. It is sometimes known as *O. candelabrum*, and more rarely as *O. brevifolium*. A vigorous plant of *O. sceptrum* bore a strong spike of soft greenish-yellow flowers, something between those of *O. Hallii* and *O. cristatum* in shape, but distinct as regards colour. The segments are blotched with a soft hazel-brown, the effect of which is peculiarly interesting. In this house *Oncidium macranthum* grows very freely, and is just now throwing up vigorous growths. A plant of *O. superbiens* var. *Enaoi* is also growing vigorously, and now bears a great branched spike of tiger-striped flowers. Another rare Orchid, *Namodes medusa*, and one with which many growers have failed, is growing here freely on a carpet of fresh living *Sphagnum*. Mr. Denning has two plants of it both doing well, and on the largest we counted nine strong "leads." This plant, when shown a year or two ago in flower, attracted much attention on account of the curious bright port wine-like colouring of its singularly fringed lip. This species is often placed on a dry block, and in such positions it invariably fails; but if the block is covered with a fresh growth of Moss, and a fair supply of tepid moisture is given at the root in conjunction with a moderately cool temperature, the difficulty experienced in growing it vanishes.

One of the Orchid-houses here faces the south, and is managed differently from the others, inasmuch as a drier atmosphere is maintained, and no artificial shading is used. We have seen this mode of treatment also carried out in Mr. Backhouse's nursery at York, and in both cases with successful results. Some small plants of *Dendrobium nobile*, which have been propagated and grown on in little baskets suspended from the roof, afforded convincing proofs that this mode of management suited them, the growth being short but remarkably plump, and of that ripe golden-yellow colour which in this species nearly always foreshadows a profusion of bloom. The plump and vigorous growth of *Laelia autumnalis*, under the same treatment, was also equally remarkable. Some established plants of *Odontoglossum grande* have become markedly altered in habit by this treatment, the leaves being considerably shorter and of greater substance than others produced in a shaded and more humid atmosphere. In both cases the size of bulb was the same, still from the stout and rigid character of their foliage one may reasonably infer that they were better developed and likely to be more floriferous than they otherwise would have been. A well-established plant of *Laelia autumnalis* was throwing up seventeen fine flower-spikes, and was one of the best examples of this species we have yet seen, while, close beside it, a plant of *Oncidium tigrinum* bore a fine three-branched spike, bearing in all thirty flowers. *Cattleya citrina*, which often battles all attempts to grow it successfully, was here literally luxuriating in the most perfect health, its pendent growth being in some cases more vigorous than that on newly-imported plants. Another delicate little plant (*Epidendrum crubescens*) was throwing up a flower-spike, and growing freely up a long slender block; and a strong plant of *Odontoglossum cariniferum* was bearing two or three stout flower-spikes. Some plants of *Laelia majalis* have made remarkably fine growth, suspended near the light; and it will interest Orchid growers to know that this shy-flowering species blooms regularly here every season, and possibly some of our readers may remember the fine variety of it which was shown by Lord Londesborough at the Royal Horticultural Society's exhibition on May 13th, 1871, and which bore three fine flowers.

Entering another house we found such a display of *Pleiones*, or Indian Crocuses as they are called, as we have seldom seen before. These are grown here in quantity, and are found almost invaluable for cut, or, to speak more correctly, pulled flowers; for, if the stem of the flower is taken between the thumb and finger and pulled gently, it comes out of its sheath with a much longer and more convenient stalk than it is possible to obtain if the knife or scissors are employed. Notwithstanding our love for novelty, we have not yet "bedded out" either Orchids or aquatics, although, in the case of the former, this might well be done in a moderately warm conservatory or winter garden by plunging pots of *Pleiones*, *Cattleyas*, *Odontoglossums*, *Masdevallias*, and other free-flowering subjects of compact growth on a fresh green carpet of *Selaginella*. For particular occasions this scheme might be adopted for a few days without injury to the plants. We have already seen this scheme well worked out by using Roman and common Hyacinths, Crocuses, Narcissus, and Snowdrops mixed with a few late-blooming scarlet *Pelargoniums* for brilliancy of colour, and the effect was, indeed, very beautiful. This

circumstance immediately suggested itself to our mind on seeing, perhaps, twenty or more pots of *Pleione lagenaria* and *P. maculata* neatly arranged in a continuous line, and supported by a row of fresh green *Isolepis (gracilis)* pygmæa backed by Cattleyas and other miscellaneous plants of larger growth. The effect of this simple arrangement was very striking. In the same house we were shown a fresh and healthy specimen of the blue-lipped *Zygopetalum maxillare*, which had produced seven spikes of flowers, and each spike was bearing from five to seven fine blooms. This is one of the best varieties of this plant which we have seen, and as a specimen it is not far behind the splendid example of it which exists in Mr. E. Wrigley's collection at Bury, in Lancashire, which at one time bore seventeen spikes, furnished collectively with 147 flowers. The pretty little *Odontoglossum Rossii* grows well here, one plant of it being nearly a foot across. This is a fine purple-blotched variety, with a broad and beautifully frilled lip. This is the purple-columned variety, and now bears eight or nine spikes, many of them being three flowered. The pretty little Cattleya Pinelli was also flowering freely in the same house; it bears rosy-lilac flowers, with a blackish-purple or velvety-crimson lip. It is of very neat and compact growth, and well worth growing as an attractive autumn and winter blooming species. A fine variety of *Zygopetalum Mackayi* bore three spikes of richly coloured flowers, the markings on the broad white lip being of the most vivid bluish-purple. Here also was a fresh and healthy specimen of the distinct-looking *Arpophyllum giganteum*, which has made a luxuriant growth, and shows well for future bloom. This fine old Orchid is sadly too much neglected; still, when well grown, it is an effective and graceful plant, either for exhibition or for purposes of general decoration. A plant of *Oncidium erosum* was furnished with twelve fine spikes of pale golden flowers, and is now highly effective; while a plant of the purple-flowered *Dendrobium Parishii* has made the finest growth we have ever seen, the newly-formed bulb being fully 18 inches in length, and nearly an inch in diameter. The old *D. cretaceum* has made growth nearly equally fine, and a plant of *D. atro-sanguineum* is in the best possible health. The latter species is one of the most difficult plants in the genus to cultivate. A pan of *Cœlogyne cristata* here, nearly a yard across, was in fine condition, reminding one of Mr. Yates' mammoth specimens, which grow in a little shady stove at Sale. It is one of the best of winter-blooming Orchids, and the plant in question promises, when in bloom, to be a perfect picture. A plant of the rare *Epidendrum amabile* bore five or six spikes of showy lilac-purple flowers, and had been in bloom for the past three months. The *Cœrulean Vanda* was furnished with a spike or two of pale blue lilac-shot flowers, and others have been cut for indoor decorative purposes. *Saccolabiums* generally do well here: some magnificent specimens of *S. giganteum* are in wonderful health and vigour, and are showing well for flower, while a plant of the beautiful old *Oncidium Lanceanum* is in splendid condition, the leaves being of a fresh green colour, without the slightest trace of the baneful spot which so commonly attacks this plant. Three fine little specimens of the rare *Dendrobium senile* deserve notice, as it only exists in one or two British collections, and is very interesting on account of its pseudo bulbs being covered with long white silky hairs. Another rare species, *D. bigibbum*, grows well here, and flowers freely. This is the finest of all the Australian *Dendrobies*; it is, unfortunately, rare, more valuable, indeed, than gold—weight for weight. Some plants of the sparkling little *Sophranitis grandiflora* were blooming freely, grown on blocks suspended near the light, and Cattleya Perrinii, a distinct and well-known plant, was very showy. Some fine masses of *Lælia anceps* were throwing up their slender two-edged scapes, indicating a gorgeous display of colour in a few weeks' time. In conclusion we may state that with but few exceptions all the plants just named were in bloom when we saw them about ten days ago, while many specimens, equally remarkable in size and vigour, are not noticed, simply because to have mentioned but half those worthy of note would have lengthened our report beyond reasonable bounds.

Marechal Niel Rose.—Those who have space to spare in their greenhouses or conservatories should plant a good strong Marechal Niel this autumn; it is a good evergreen climber, as well as one of the most useful plants that could be put on a conservatory wall, and one which will also be useful for furnishing cut blooms.—H. G.

Fruit of Tacsonia Van Volxemii Eatable.—I have met with several people lately who were under the impression that the fruit of this beautiful flowering greenhouse climber was not edible. That is, however, a mistake. Its fruits, which somewhat resemble those of *Passiflora edulis* in form and flavour, are even more palatable than the fruit of that Passion-flower, and may be used at dessert in the same way. As a fruit-bearing plant, it is even more to be recommended than the *Passiflora*, inasmuch as it ripens fruit in a cool house, and produces it for a long time in succession. Old plants of it fruit more freely than young ones. An old plant of it which covered a large space on the roof of the show house—No. 4—at Kew a few years ago, produced fruit annually in abundance.—J. Mura.

THE FLOWER GARDEN.

INSECTS AND COLOUR IN FLOWERS.

MR. BOULGER correctly attributes to me the opinion that the development of beauty is an "object in Nature." He thinks it a fallacious opinion: so I suppose does Mr. Darwin. I hold that opinion advisedly, however, and believe that the rejection of it is a constant source of error in Mr. Darwin's books, for which otherwise I have the profoundest respect and admiration. I do not dispute that colour may be attractive to insects, or that the reproduction of plants may be assisted by it; but I reject the doctrine that the colour would have no *raison d'être* if insects were exterminated, and I believe that Mr. Darwin's theories upon this point are not sufficient to explain his own facts, or such other facts as are revealed by Mr. Comber's curious researches into the dispersion of coloured flowers. I do not see any reason to doubt that if all flowering plants had been propagated by buds and stolons only, as some plants practically are, the world at this epoch would still have known the beauty of flowers, although probably, with less variety of form and colour. It is part of the natural development of the wave of life, as sure to be produced, when the total conditions are ripe for it, as leaves in the spring, or as *Lycopods* in the coal age and *Conifers* in the oolite. The law of natural selection expresses truly enough the interaction of forces in the great heaving life-sea, but the forces are not increased or diminished by it, only modified in their lines of motion, the course made clear for one and obstructed for another; here a union of similars, and there a neutralisation of opposites; while each works out a destiny of its own as an individual wave, and shares the common destiny of some larger wave of which it is a constituent part. What insects do in relation to the colour of flowers is to modify the conditions, so that the force, which has already begun to show its tendency to develop colour, may get freer play, and in each generation approach nearer to its climax. The many instances in which colour is developed independently of insects seem to me to show quite conclusively that the colour-producing force which exists in the plant will break through all obstructions whenever the opportunity is presented. Sometimes increased richness of soil will furnish the necessary condition; sometimes a higher temperature; sometimes cross-fertilisation; sometimes the care and selection of man. This law holds good throughout the organic world, and accounts for colour wherever it is found. The Darwinian doctrine of mere utilitarianism is driven to the strangest devices in its attempts to do the same thing. Mr. Boulger speaks of the development of corolla at the expense of stamens as a "degradation of organs," and regards it in the light of a disease. Many botanists would agree with him, no doubt. But where is the proof of this? Is a plant produced for the mere purpose of re-production? Is that even its highest purpose? Whatever beauty may be, the reproductive process is assuredly a means, and not an end. There is some ground for the hypothesis that the flower of a plant represents its nervous centre, that it is the analogue, perhaps even the homologue, of the brain and countenance of the higher animals. In vegetables the reproductive organs are associated with this nervous centre. But they are not so placed in animals, and if they had been otherwise arranged in vegetables the blossom might still have been the crowning beauty of the plant. I do not admit that the metamorphosis of stamens into corolla is a degradation at all. I am not sure whether the production of perfectly double and perfectly barren flowers ought not to be regarded as the final goal of every species of plant—the point at which reproduction becomes no longer necessary, because the life-wave of that species has reached its climax and needs no further to be carried forward from generation to generation. Finally, the point at issue amounts to this: Is colour in flowers a mere expedient for getting them cross-fertilised? or is it a natural and necessary phase in the development of plant-life, which serves also the secondary purpose of securing the advantage of cross-fertilisation; as the brain of man, which is primarily the great organ of thought and sentiment, serves also the secondary purpose of selecting wholesome food? I hold to the latter view, which includes and accounts for all that the other does, and much besides.

F. T. Morr, in *Nature*.

THE VIOLET AND THE NAPOLEONS.

THE 15th November is the Empress Eugénie's fête day, and Violets became perceptibly dearer in Paris on that day during the Second Empire, when there was a perfect Violet ovation; bunches of Violets, not in hundreds, nor in thousands, but in tens of thousands, being thrown through the iron railings of the courtyard of the Tuileries. The palace servants piled them up into enormous pyramids, which reached as high as the first-floor windows; the various doors were decked with them, and the great central balcony,

from which the Empress greeted the people, seemed absolutely made of Violets. The Violet came to be chosen as the badge of the Napoleonic dynasty during the early days of the present century, when the great general, who, as he himself boasted, carried the fate of France and Europe at his sword's point, had already been elected First Consul for life, and was rapidly advancing towards the Imperial throne. His wife, Josephine, was living at Malmaison; while he himself inhabited the Elysée, and rode almost every day to Malmaison, accompanied only by a single servant, or perhaps by the faithful Rastan. One February morning, on his way to Josephine, he rode faster than usual, being late. The cause of his delay had been a bouquet of Violets, expected from Versailles, and which had not arrived. In those days Violets in winter were rarities, and it was impossible to get them from ordinary gardens. Bonaparte, however, had a promise to perform; it was Josephine's fête day, and, when a few days before, he had asked what present he should bring her, she had replied, "only a bouquet of Violets." Was it possible he might not be able to fulfil this simple request—he who a year later was to present her with an imperial crown! Two messengers had already been despatched to Versailles; Bonaparte was worse off than Louis XIV., he was obliged to wait. At the last moment he received from an unknown hand a magnificent bouquet of Violets, ten times more beautiful than the Versailles flowers would have been. The consul was surprised and touched—could he guess the giver? Galloping to Malmaison, he found that the friends of the family, who of course were many, had already brought splendid presents; but, embracing his wife, he only presented the promised bouquet. Napoleon's great love for Violets dated from this incident. That particular bouquet was taken care of like a pet child by his special desire. When at length it faded, Josephine, although she could not comprehend her husband's sudden passion for Violets, took care to procure fresh ones; and after she became Empress, she had Violets always about her. Afterwards, when a fatal policy had thrust her from the Throne, and she had retired desolate and unhappy to Malmaison, gardening was her favourite occupation, and the Violet her favourite flower. And when, after a few years, she died of a broken heart, Violets were planted on her grave; and they bloom around the mausoleum which has been erected over her last resting place. Even at Saint Helena, Napoleon planted Violets; and when his coffin first touched French soil at Cherbourg, it was covered in a few minutes with bouquets and wreaths of Violets. Under the Restoration, the white Lily once more raised its head, and under the prosaic government of July no one troubled himself about flowers; but with the Second Empire the Violet regained its place of honour. In November, 1858, there was great excitement throughout Paris, for the president of the new republic was about to be elected. The sad days of June were still fresh in the memories of all; and the future fate of France appeared more than ever uncertain. Everyone anxiously wondered whose name would head the list—whether the new ruler would be Cavaignac with government by the sword, Louis Blanc, or Ledru Rollin, with socialism or communism, or, finally, Louis Napoleon with a second Empire. The Prince was walking uneasily up and down a room in the Hôtel du Rhin, in the Place Vendôme. On the chimney piece and window sills stood costly vases filled with Violets—an attention of the landlord's, which in after days was not forgotten by the Emperor. A few faithful followers surrounded him—Persigny, Morny, Dr. Conneau, and others. "These flowers are a sign of good fortune," said the Prince to Persigny, as he pointed to the Violets, and already a tumultuous crowd was on its way from the Hôtel de Ville, where the adding up of the three million votes had just been completed; nine-tenths being for Louis Napoleon.

Flower Gardening at Stukeley Hall.—When on a visit, a few days ago, to Stukeley Hall, the residence of P. Tillard, Esq., I noticed a very pretty bed planted as follows: The ground-work was composed of Veronica Imperial Blue intermixed with dwarf plants of Abutilon Thompsoni, fine in colour. Although the beauty of other beds in the gardens had departed, this was in great perfection, and produced a very pleasing effect. Both the Veronica and Abutilon will stand several degrees of frost without sustaining any injury; in fact, two large old plants of the Abutilon stood out here unprotected last winter, although we had in February 17 of frost. Of course the young growths were killed; but they broke strongly from the old wood in spring. I should state, however, that they were in rather a sheltered position. At Stukeley, like many other places that have come under my notice, foliage, or carpet bedding, is in the ascendant, and Mr. Hopkins, the intelligent gardener, had used for that purpose, in his different designs, most of the plants usually met with in the London parks. Stukeley has also acquired, at the local shows, a reputation for its Roses, which are grown in considerable numbers.

Mr. Hopkins is in favour of dwarfs on their own roots, and, to carry out this idea, he is gradually removing all standards, as Roses on their own roots are unquestionably more lasting. The soil, a heavy loam on clay, when properly manured and cultivated, is well fitted for Rose culture. Mr. Hopkins uses largely burnt clay or earth for opening and improving the staple of this heavy land—an example that might be advantageously followed elsewhere, both for flowers and vegetables.—E. HODDAY.

An "Alpine bed."—I venture to ask if you would tell me in the next number of THE GARDEN the best arrangement for an Alpine bed, 12 feet in diameter, as a centre to our flower garden. The bed is at present in two tiers, edged with Fir piles. These would be removed, and the bed lowered, but, as I imagine it would be too large to plant like fig. 27, in "Alpine Flowers," which I have, I should be greatly obliged for any instructions as to whether it would be well to keep it in two divisions, and how you would advise the bed to be arranged to look best. The surrounding beds are filled with bedding-out and foliage plants.—E. C. H. [The instructions in "Alpine Flowers" almost meet the case. Use no formal edging of any kind, and avoid all divisions. The essential point is to have a mass of good free soil; from this allow a few good stones to crop up, taking care that the base of each is buried, and the best side exposed. Use no rampant-growing plants, for which gardens are best fitted. The dwarfest and choicest plants are generally best kept towards the upper parts of the rocky bed. Such a bed should be wholly kept apart from ordinary bedding arrangements.]

Grafting Roses on Wild Stocks.—M. Carbon, writing in the November number of the *Revue Horticole*, makes the following interesting and instructive remarks on the grafting of Roses on wild stocks. He relates that, having grafted some fine new kinds of somewhat delicate, indeed weakly, growth, on very robust stocks, with the purpose of supplying them with the vigour which was wanting in their natural constitution, he was entirely disappointed in the result, nearly all the grafts so treated having perished. It would appear that they were over led by the profuse sap of the robust stock, and positively perished by a kind of surfeit, and the experimenter, M. Carbon, infers, therefore, that Roses of delicate growth should be grafted on stocks of analogous constitution to their own. M. Carbon announces another interesting result of his careful observations on Rose grafting. He tells us that, having subsequently grafted some other kinds on wild stocks of similar robustness to their own, that they succeeded well, the grafts throwing out long and healthy shoots. To give them still more strength, however, he rubbed off all the coming shoots of the wild stock; but, to his surprise, found that the previously fine growth of the graft soon began to dwindle instead of showing increased vigour after this operation; and, in another experiment, therefore, instead of destroying all the shoots of the wild stock, he only suppressed those of the grafted branch, allowing wild shoots to remain and flourish on the stock above the grafted branch, and this experiment proved entirely successful. M. Carbon considers that, in this instance, the shoots of the wild stock above the graft served as sap-tractors, drawing up a good supply of sap past the grafted branch, which naturally partook of the supply thus brought, as it were, to its door.—H. N. H.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Crocus odorus.—This is a pretty slender blue-flowered species well worth a place on any warm snug border. It is just now in bloom at Kew, bearing pale sky-blue flowers with deep orange anthers.

Cleaning Statuary, Vases, &c.—It is recommended, in cleaning Moss-covered statuary in gardens, &c., first to kill the vegetation by the application of petroleum or benzine, which will not injure the stone, and to remove it when dried by brushing, and, finally, rubbing with a rag.

Geranium Robertsonianum album.—I am very fond of this pretty little white-flowered plant, which, to my way of thinking, is far brighter and more effective than the common pink-flowered form. It is just now flowering on the rock-work at Kew, and well deserves a place in a similar situation in other gardens.—B.

Fortune's Saxifrage a Good Autumn-blooming Plant.—To anyone in search of good autumn flowers, I would recommend Saxifraga Fortunei. It is now very pretty, both in foliage and flower. It is perfectly hardy; it will be cut down by the first frost, but will come up again in the spring. I think it would be very effective as an edging plant.—HENRY N. ELLACOMBE, *Bilton Vineage, near Bristol*.

A Wild Garden on Stiff Soil.—What should I do with about half an acre of stiff land which I have destined, from its sequestered and sheltered position, for a wild garden as described in Mr. Robinson's book? How can I best prepare the soil for such a purpose? Will it be desirable to diversify the surface with some mounds, or are these on such a soil likely to get too dry?—A. C. R. [There are so many vigorous hardy flowers in cultivation that enough could be selected to form a charming wild garden on almost any soil. In stiff soils the numerous Asters and Golden Rods, many Pea-flowered plants, the Evening Primroses, Spurgeons, Buttercups, Globe-flowers, Statice, Iberis, Anubrietas, &c., and many other plants do well. If, however, you prefer to make the ground better in other ways you can, of course, enjoy a greater variety. Diversify, by all means avoiding the stiff, ugly, and formal banks and mounds commonly seen where artificial diversification of ground is attempted by incompetent persons.]

THE GARDEN IN THE HOUSE.

A TABLE VASE OF AUTUMN FLOWERS.

It has often been laid to my charge that I am the exponent of a style of table-decoration which is too costly for the million. I believe that it has been my good fortune to have had opportunities, which but few others have enjoyed, of arranging flowers and foliage which, from their rarity, are not often procurable even for love, much less for money; and, if I have been guilty of occasionally endeavouring to convey to others some of the pleasure which the best of these arrangements have afforded myself, the offence will, I trust, be generally considered to be neither unnatural nor unpardonable. Lest, however, it should be supposed that nothing short of Orchids and Gleichenias will satisfy me, I send you a description of a large vase which occupied the centre of a round dinner-table, 7 feet in diameter, and which was furnished at a cost of 10s. from purchases made in Covent Garden Market. The bill was as follows:—Ferns, 3s. 6d.; German Asters, 1s. 6d.; Gladiolus, 1s. 6d.; Pink Geranium, 1s.; Fuchsia, 1s.; Cyperus, 1s.; Snowberries, 6d. The following was the plan on which they were arranged:—At the bottom, a fringe of dark green fronds of *Polystichum aculeatum*; in the middle, a fringe of smaller and paler green fronds of the same Fern, mixed alternately with good fronds of Maiden-hair; at the top, a light fringe of *Pteris serrulata*. The flowers in the bottom dish consisted of purple and of deep crimson Asters, arranged in an irregular circle, with here and there a white one. Within this circle reclined three spikes of scarlet Gladiolus, placed obliquely and spirally, under the shade of three fine umbrellas of *Cyperus alternifolius*. Two or three light fronds of *Polystichum* and Maiden-hair finished this part of the vase. In the middle dish were used Asters of smaller size, chiefly pink and white, with here and there a smaller purple one for contrast. Outside of this ring were placed, at irregular intervals, some small branches of Snowberries (*Symphoricarpos racemosus*), which drooped over the fringe. Inside the circle of Asters were a few scanty trusses of pink Geranium Christine, partially concealed under some pieces of green *Cyperus*. The trumpet-shaped vase at the top was surmounted with a spike of white Fuchsia with a red corolla, while some small lateral branches of the same hung over the edge. Besides these, there were a few trusses of Christine, some pieces of Snowberries, which had their branches supported by fine stiff wire to keep them upright, and a few fronds of Maiden-hair. The whole was lightened and finished by the introduction of half-a-dozen sprays of climbing Fern. Amongst autumnal decorations, I have seldom seen one which pleased me more, and I am much

indebted to Mr. Burbidge for the assistance which his carefully executed drawing affords me in explaining the arrangement of the flowers, and in conveying the effect produced. Although a vase of these dimensions may be too large for dining tables of ordinary width, it would look well either on a sideboard or in the centre of a drawing room. W. T. P.

HAND BOUQUETS.

NOTHING requires more taste or skill in its arrangement than a well made and effective hand bouquet. As a rule, unexperienced persons employ as many flowers and Ferns to make one hand bouquet as a professional bouquet maker would make three out of with ease. The reason of this is, in home-made bouquets (if I may be allowed to use the expression), the flowers are hardly ever mounted on wires, but are left on their own stems. Doubtless, they remain longer fresh in that way, but who requires a bouquet to keep fresh more than one evening? Each flower, or truss of blooms, as the case may be, which has a long stem, should have it cut off with the exception of, at most, about 2 inches; these stems should then be bound to a stub wire, the wire being bound up nearly to the flower, so as to support the stem the whole way, otherwise the flower might be liable to break off above the stub. Before finishing off binding the stub and stem together—indeed, just after one or two twists of the binding wire have been given—a little damp moss should be placed round the stem of the flower, and then bound round with the binding wire. This keeps the flowers fresh the whole evening, and should be applied to every flower and Fern that is used in a bouquet; when making one, therefore, after the flowers have been wired, the next thing is to bind them to the stubs, as has just been described. All being prepared and ready to hand, the next thing is the making of the bouquet. Some seasons it is the fashion to have bouquets very large, while in others they are of much smaller dimensions; but the proper size may be determined by taking a peep into some first-class florist's window. It is almost impossible to learn to make hand bouquets by means of printed directions; by far the best plan is to see one made. The way in which I myself first learned to make band and button-hole bouquets was by watching how they were made in the shops in Covent Garden Market. My first attempts were very poor indeed, but I persevered and many a prize have I taken for them since. All bouquets are finished off with a fringe of Ferns round the edge, the most suitable for this purpose being *Adiantum cuneatum*, a few fronds of which should stand up through the flowers in the bouquet. This tends to give it a light effect, a point to which as much attention as possible should be paid. Bouquets are always finished off by a paper frill, the pierced work round the edge of which should be as handsome as possible when lace is not employed; papers are sold with lace attached, but these I do not approve of, as, when lace is used, it should be real and handsome, and bear looking into; that sold attached to the papers is only imitation and much better dispensed with altogether. The only imitation lace which looks well for this purpose is Blonde, but in any case the best plan is to tack on the lace to the

A Vase of autumn flowers.

paper yourself, when you can select what kind you please. A bow of ribbon and two long ends are often tied round the stems of bouquets, outside the paper or wicker shield, which keeps damp from coming through and spoiling one's gloves. If for a bride's bouquet, the bow and ends should be of pure white ribbon, satin or corded according to taste. I myself prefer the latter, as being more elegant. For a ball or bridesmaid's bouquet, if of white and scarlet or blue and white, or any other colour selected with white, half of the bow and one end should be of white, and the other half should match the colour in the bouquet. I have seen this look particularly elegant where the bouquet was made of mauve and white flowers. As a rule, I think lace round the edge more suited for wedding bouquets than those to be used on other occasions. For sending a bouquet a short distance, basket cases are sold, which prevent their being crushed. "Bouquets for the hand" (says a contemporary) "should be made of the choicest flowers, gracefully arranged; heavy solid flowers or massive arrangements should be as much as possible avoided. Such bouquets are necessarily brought under the closest inspection of the eye, and should be composed of flowers of delicate structure of great variety, and exquisite fragrance. The present style of immense size, composed of solid flowers, scarcely if at all relieved by foliage, is only suggestive of some enormous variegated or pied Fungus, hung with silk fringe, or put up in lace paper. When carried at evening entertainments, they frequently appear to be a burden to their possessors. For successful effect in floral decorations much depends upon the judicious arrangement of colour; violent contrasts are also to be avoided, as is also the sameness produced by having too much of one colour. In producing harmonious contrasts of colours, it should be remembered that there are only three primary colours—red, blue, and yellow. From these arise what are called the binary or secondary colours, namely, orange composed of yellow and red; purple, composed of blue and red; and green, composed of yellow and blue. These form contrasting colours to the primary three with which they are in harmonious opposition, as the orange with blue, purple with yellow, and green with red. From the combination of these secondary colours arise three tertiary colours—olive, from purple and green; citron, from green and orange; and russet, from orange and purple. These tertiary colours harmonise with the primaries, as they stand in the relation of neutral tints to them, but are in harmonious opposition to the secondaries, from which they are combined. Red, blue, and yellow harmonise with each other, and they may be placed in juxtaposition, but purple should not be near red or blue, as it is composed of these two colours; for the same reason, orange should not be placed next to yellow or red, the rule being that no primary colour should be brought into contact with a secondary colour of which itself is a component part; nor any secondary colour brought into contact with a tertiary colour of which it is a component part. Another rule is, that the secondary and tertiary colours, and the neutral hues arising from combinations of the tertiaries, such as brown, maroon, puce, slate, lavender, &c., should be used in the greatest quantities, and the primary colours used in smaller quantity for brightening the effect. If you lack the proper shades for producing the necessary harmonies, and find that two colours do not harmonise well, separate them by a white flower. Again, always place the brightest colours in the centre of your design, and gradually decrease the intensity of the tints as you approach the exterior; and avoid spottiness or patchiness by using as much as possible one prevailing colour." I always place in the centre of my bouquets a Rose, Camellia, or some such flower. One of the prettiest bouquets I think I ever made was arranged as follows:—In the centre was a white Camellia, then white Azaleas, Stephanotis, Gardenias, Woodruff, and a rich mauve-shaded Cineraria, Lily of the Valley being spiked over the whole, together with blooms of Dendrobium nobile and fronds of Adiantum cucuatum, a fringe of the latter being formed round the edge. The whole was finished off by a handsome paper, and a bow and long ends of mauve and white corded ribbon.

Sprays for the Hair.—Elegant sprays of natural flowers may be mounted for this purpose with little trouble, and are far prettier than the artificial ones mostly used. A little damp Moss or cotton-wool should be bound round their stems to keep them fresh, or it is a good plan to insert the ends in a small glass tube, such as is sold for coat flowers (the sharp hook having first been removed). This can be easily concealed amongst the braids of the hair, and in this manner flowers will keep fresh the whole evening. A. HASSARD.

Growing the Chrysanthemum for Table Decoration.—I venture to send you my practice as regards growing dwarf, starchy, well-flowered Chrysanthemums, suited for both table and conservatory decoration. I do not advocate the 6, 8, and 10 feet scale of

growth, excepting for cut flowers. I take cuttings from old plants about the middle of July, and insert them in boxes or hand-lights exposed to the open air, and when these are rooted I pot them off into 60-sized pots, using a compost of one-third leaf mould and sandy loam, well-decayed manure, and plunge in ashes; I syringe freely and water with liquid manure. When the shoots have grown 2 or 3 inches in length I pinch them back to whatever shape the plant may be required. As soon as the plants have become well rooted in the 60-sized pots they should be shifted into 54's or 48's well crocked, using the same compost as before, and again plunge. At this stage of growth, to retard their growing tall, they must only be watered to keep them from flagging. Protect from frost under a hand-glass, raised to give a circulation of air, and discontinue the application of manure-water when the plants are in flower. I can thus have plants 1 foot in height (including the pot), flowering profusely, and furnished with foliage to the pots. This may be considered unnecessary trouble; but, with such results, I feel amply repaid. The kinds I find most useful are Cassy, Duke of Edinburgh, General Harding, Mrs. Morgan, Jardin des Plantes, and Cedo Nulli.—A. J. O., Felcourt.

GERMINATION OF SEED.

THE *Flore* says that two chemists of the Academy of Brussels, Messrs. Dehćian and El. Landrin, have made some interesting discoveries relative to the germination of seed. It is well known that the action of the air and the presence of water are necessary conditions; but hitherto the mode of action of these two agents has not been understood. MM. Dehćian and Landrin have been enabled to throw some light on these mysterious phenomena. It is now ascertained that the effect of water is to soften the covering of the seed so as to render it permeable by gas. When they have imbibed sufficient moisture, the tissues of the seed acquire the property of condensing gases. This condensation cannot take place without producing heat; the oxygen, therefore, which has penetrated the tissues is sufficiently heated to cause oxydation and the consequent awakening of vegetable life. According to the experiments of MM. Dehćian and Landrin, the condensation of the gases in the seed is the first commencement of germination. If this condition is not produced, whether from want of water or because the air cannot reach the seed, there can be no formation of the immediate principles necessary for the evolution of the germ. These experiments, although highly scientific, are very interesting from a practical point of view, as they enable the cultivator to determine the influence which the solidity of the soil, the dryness or the excess of moisture, the depth of earth in which the seed is placed, may have on the success of the sowing. Experience has already taught us much on these matters, but scientific methods, corroborating, as they do, the observations of practical men, can alone point out the sure means to be employed to bring about the desired results. W. N.

THE JOVIAL VEGETARIANS.

AIR—"Fill a Bumper Fair."

Fill the saucepan fair,	Sweet is the Seakale,
Friends are asked to dinner,	Stew it slightly quicker;
Shred the Beans with care,	Draw us Adam's ale,
Slice the Carrots thinner,	'Tis the best of liquor,
Mash the Turnips well,	Potatoes please to steam,
Cream improves their flavour;	For every one a plateful;
How nice yon Pea-soup's smell!	And prithce do not dream
How dainty is its savour!	The guests will not be grateful.
<i>Chorus.</i> Fill the saucepan fair, &c.	<i>Chorus.</i> Fill the saucepan fair, &c.
Celery you have bought,	Now, for the bouquet
Clearly you have reason,	Cut a Cauliflower,
'Grass I would have sought,	Sweet as new-mown hay
But 'tis not now in season.	Sprinkled with a shower.
Cabbage?—by all means,	Then with cheerful smile
Brussels Sprouts we'll give too;	Go and mix the salad;
Men who live on greens	I at ease the while
A green old age may live to!	May warble you a ballad.
<i>Chorus.</i> Fill the saucepan fair, &c.	<i>Chorus.</i> Fill the saucepan fair, &c.

—Punch.

Floating Gardens.—Artificial islands are, it seems, common in China, as well as in Mexico. "The Chinese fishermen" (says Barrow's "China") "having no house on shore, nor stationary abode, but moving about in their vessels on the extensive lakes and rivers, have no inducement to cultivate patches of ground which the pursuit of their profession might require them to leave for the benefit of another; they, therefore, plant their Onions on rafts of Bamboo, well interwoven with Reeds and long Grass, and covered with earth, and these floating gardens are towed after their boats."

THE FRUIT GARDEN.

TESTING GRAPES.

AMONGST the many comforts and enjoyments that glass has given us, we may well rejoice in that one which enables us, in this dull month of November, to sit warm and secure from wintry blasts under the shade of our own Vines and Fig trees. Summoned by a neighbour to taste and pronounce an opinion on the merits of the products of his glass-covered Vineyard and orchard, the advantages alluded to as being conferred by well-erected glass structures were very fully evidenced; we tasted the Grapes that hung about us, and noted their qualities and peculiarities, and we were so fortunate as to have the opportunity of contrasting the merits of Mr. Pearson's new Grapes with the old-established and approved kinds. The notes thus made apply to the Grapes we had before us; other soils, situations, and culture may modify the sorts commented on, but as we tasted and thought, so we decided. Our opinions may, therefore, be of some use and interest to intending Vine growers.

Muscat Champion.—This is not so much known or appreciated as a Grape possessing so many good qualities deserves to be. I presume that the reason it is so seldom seen in collections is the fact of its peculiar colour, a 'grizzly red,' but I do not know that a Grape need necessarily be white or black. A badly-coloured Hamburgh is held to be a discredit to a cultivator; and that may be, but there is a richness in the tint of colour in this Grape that separates it from an ill-coloured Hamburgh, and makes it really a desirable addition to an artistically disposed dish of Grapes. The Muscat Champion produces a long, rather thin than massive, bunch, not much shouldered; the stalk is thick and fleshy; berries, large as a Mill Hill Hamburgh. In quality the Grape is juicy, melting, slightly flavoured with the Muscat aroma, but still sweet and refreshing; the berry is thin-skinned, the flesh not adherent to the pips. The Vine is a vigorous grower.

Royal Ascot.—A free-growing and free-bearing black Grape; berries, oval, black, large; pips leave the flesh; bunch, medium-sized; berries, irregularly clustered, one-shouldered. An agreeable vivacious Grape, without any pronounced aroma, and, therefore, suitable to most palates; very firm and rather strong skin, and short foot-stalk.

Chaptal.—A cross between Chasselas de Fontainebleau and Muscat, partaking of the first-named parent in the greatest degree, producing freely its thin Muscadine-like wood; bunch, medium-sized; berries, of an amber colour when well ripened, less viscous in flesh than Chasselas. A Grape not without recommendations.

Madresfield Court.—Free, as regards habit of growth, and prolific; bunches, moderately large; berries, oval, black, medium-sized, rich refined Muscat flavour. An excellent Grape in many respects, but requires special treatment and a house exclusively devoted to it, in order that its best qualities may be developed. It will not hang so long as Muscat of Alexandria.

Mrs. Pince.—A free-growing and distinct Grape, producing, under high culture, large bunches; berries, oval, black, strong skin, firm flesh, slightly flavoured with the aroma of the Muscat. Not adapted for general amateur cultivation. It has the merit of keeping well.

Lady Downes.—A Grape that is found to thrive in some localities, and under certain modes of treatment, and to fail altogether in other places. Under congenial treatment it produces large bunches, medium sized black berries, the skin of which is thick; it has no marked flavour. It hangs well. It is a variety very liable to be affected by mildew.

Muscat of Alexandria.—Still unapproachable in regard to those great recommendations of a Grape—constitution, free habit of bearing, quality, and size of bunch; the shades of difference between the varieties of Muscat, such as Charlesworth Tokay, Bowood, and others are too slight to be readily distinguished. When well ripened, the rich golden colour of the fruit, the handsomely formed bunch, and the luscious aromatic sweetness of the berry, constitute it the first in the list of English hot-house Grapes; no Grape hangs better. It may be preserved on the Vines until April.

Black Alicante.—The variety grown in the Newark Vineries differs in the form of berry from some others bearing the name. It was obtained from Mr. Merrideth. The berries of this variety are nearly round, other kinds are oval. Mr. Ingram, of Belton, raised many seedlings from the old Alicante, and these were distributed, and this may account for the differences found in the so-called Alicante. This kind produces a large and massive bunch, the berries moderately large, intensely black, and covered with a fine bloom; the skin is thick, flesh melting, and not perfumed. It is one of the best and hardest late keeping Grapes.

Raisin de Calabre.—This has the merit of being free in

growth, and producing large bunches. When well ripened it has a golden tinge. It has no marked aroma, and is, perhaps, less meritorious than the White Nice.

Ferdinand de Lesseps.—A Grape obtained by Mr. Pearson, from the American race of Vines; by a cross with Muscadine, a blending of the two flavours is found combined with a sweetness and aroma peculiarly its own; it is the most distinct and peculiar Grape we possess, and is probably destined to furnish a new character, if not a new race, of Grapes; its intense, almost cloying sweetness, and marked aroma make it objectionable to refined palates; it is rather small in berry and bunch under ordinary culture.

Mrs. Pearson.—Bunches of this variety, with Golden Queen and Mr. Bass, were courteously sent by Mr. Pearson, on the solicitation of Mr. Newton, and were, with the older kinds, duly tasted and discussed. The bunch produced by Green Queen is symmetrical, and will, probably, be large under special culture. The berries are greenish, slightly oval, of medium size; skin, tough but not thick; flesh adherent to pip; in quality the Grape has an agreeable freshness, with a slight "suspicion" of one of the characteristic peculiarities of Lesseps—an aromatic sweetness. There is a distinct character and quality about this Grape that will secure it a place in our collections.

Golden Queen.—The bunch sent to us was of medium size and handsomely proportioned, the berries hanging on thick close foot-stalks. The Grape in colour is a rich amber, like the Muscatel of shops; it is excessively sweet, with a distinct aroma that is not Muscat, but reminds one of de Lesseps without its cloying sweetness; the skin is strong without being thick, the pips not adherent; the Grape, altogether, has a very promising combination of good qualities that ensures it a great future, and its rarer position amongst the raisers of good fruit. The Vine is said to be hardy, and excessively prolific.

Mr. Bass.—A direct seedling from the Alicante, with all the external peculiarities of size and colour, perhaps more oblong in berry than the Alicante, tough strong skin, and sweeter than its parent, juicy, not too fleshy, and is of free growth, and, with the keeping properties of the Grape from which it is derived, likely to be an acquisition.

W. INGRAM.

Belvoir.

RIPENING PEARS.

PERHAPS no kind of fruit is more influenced by the season than Pears, both as regards flavour and time of ripening. The soil of the kitchen garden here is of a very strong adhesive loam, with a red clay sub-soil; the very dry and warm summer has, therefore, just suited the Pear crops, which have been the most abundant this year that I have ever grown. Perhaps a list of the best early, mid-season, and late Pears, and their times of ripening from the open borders, may be of interest to the readers of THE GARDEN. The first variety in ripening was the Doyenné d'Été in the middle of July, and when grown on the Quince-stock, as a bush or pyramid, it is very ornamental in colour and good in flavour; but on the walls it was worthless with me, and not deserving of a place there. The Citron des Carmes is another good juicy early Pear ripening early in August, and is worthy of a wall in cold districts. The Beurré Giffard is one of the very highest flavoured of early Pears when grown as a bush on the Quince-stock; it ripened with me in the middle of August. That old favourite sort, the Jargonelle, double grafted on the Pear-stock and grown as a pyramid, ripened with me an excellent crop in the end of August, being as juicy and good flavoured as any from the walls. Madame Treyve, an excellent, high coloured, and good flavoured early Pear, ripened here in the middle of September, and bears well as a bush on the Quince-stock. Summer Beurré d'Arenberg, a small-sized but delicious Pear, ripened with me in the middle of September. Louise Bonno of Jersey is one of the best old favourite Pears grown, and has borne with me enormous crops, both on pyramids and on a wire-trellised arcade. Perhaps this variety, when grown as a bush on the Quince-stock, is higher coloured and better flavoured than when grown in any other way. It first ripened here this year in the end of September. The Comte de Lamy is a medium-sized but most delicious autumn Pear, and ripened here in the first week in October. The Beurré Bose, another rich perfumed Pear, has never ripened here before; but on a wire trellis this year's crop has been abundant, and the fruit large in size and excellently flavoured, and they ripened in the middle of October. The Gansel's Bergamot is well known to be one of the best flavoured of all Pears, and is, in general, only a shy bearer, but here, on a wire-trellised arcade, three large trees on the Pear-stock have borne very excellent crops; the fruit has likewise been very large for the sort, and of a far richer aroma than any gathered from the walls. The Beurré Superfin, in the same arcade, has likewise borne very fine crops, and of excellent flavour, the season of ripening being in the end of October. Beurré

de Caen, synonymous with the old Brown Beurré, has ripened well on this trellis for the first time, and proves to be an excellent late October Pear. The Beurré Hardy is another excellent melting Pear, and bears on the Quince stock as a bush or pyramid; it ripened here in the beginning of November. The Fondante d'Automne is a small delicious melting Pear, ripening in the first week in November.

Welbeck.

WILLIAM TILLERY.

THE BLACK ALICANTE GRAPE.

I AM so favourably impressed with the merits of this Grape that I consider it well worthy special notice. A few years ago Black Lady Downes was everybody's Grape who required or desired a late variety; but so few are able to combat successfully with the scalding which annually deprives the bunches of the best of their berries, that many, if not rooting it out altogether, are certainly not increasing their stock of it; many intending planters are, therefore, on the outlook for a late Grape that will with certainty repay them for any care and expense that may be bestowed upon it. But, were matters not as bad as has just been stated, I am of opinion that Black Alicante would still be preferable to Lady Downes under the most ordinary treatment; provided there is a good border, the Alicante will succeed better than any other Grape with which I am acquainted. When the bunches are newly formed, and up to the time when they are coming into bloom, they are extremely small and unpromising, but, after the berries are fairly set, they swell out in a wonderful manner, and invariably form handsome bunches, which weigh from 2 lbs. to 6 lbs. each. The berries set more thickly than those of any variety I know. I never yet saw an imperfectly set bunch of it, and this in itself is a recommendation which should not be overlooked. From the time the berries are set until they are thoroughly finished they exhibit no flaw or blemish; on the contrary, they colour well, and become covered with bloom. This variety will bear with impunity a heavier crop than any other kind I have seen tried in that way. In short, a weight, under which others would shank and shrivel, is unflinchingly borne by the Black Alicante; and, whoever heard or saw this variety not colouring through excessive cropping, or any other cause? while its flavour, which is the main point in the case of all Grapes, is second to none in mid-winter, and, though much thinner in the skin than Lady Downes, it keeps as long in perfection as that variety. Altogether, it is a most excellent Grape.

J. MUIR.

PEARS WORTH GROWING.

I FIND but little to dissent from in the descriptive list (see p. 155) of Pears furnished by my old friend, M. Ferdinand Jamin. Having the great advantage of a knowledge of both English climate and culture, and a perfect acquaintance with that of France, his estimate of Pears is particularly valuable and correct as applicable to this country, and his information about the selection of Pear-stocks is calculated to be useful to those engaged in the cultivation of Pears. What he says in recommendation of Beurré Superfin and Beurré Hardy is emphatically true; they are Pears of great excellence. But, alas! they ripen so quickly after gathering, and take a bruise so easily, that our rough-handed dealers would never be able to present them in a tempting form. A Pear sent to me under the name of Beurré d'Anjou, by Mr. Rivers, is called No Plus Meuris in M. Jamin's list. The kind grown in this country as No Plus Meuris differs essentially from Beurre d'Anjou, which is large, well-formed, and altogether one of the best and handsomest Pears I possess. Our No Plus Meuris is a hardy, prolific, late-keeping kind, seldom shapely, and not always good. I endorse everything that is said in commendation of Doyenné du Comice. Passe Colmar, grown on a south and east wall with me, does not deserve the encomiums bestowed upon it by M. Jamin. It is generally small, and never first-rate in quality. Orpheline d'Enghien is a very useful Pear, seldom failing to produce a crop; it is a juicy and refreshing kind, and keeps after ripening. I have finited Olivier des Serres two years successively, and I like it exceedingly; it keeps well, and its flesh is particularly soft and mellow. It is a very distinct Pear, being strongly russeted and irregular in shape. There is one Pear which M. Jamin only mentions in his list of Pears for walls which deserves notice. It is one I originally received from him under the name of Doyenné d'Alençon; it is a Pear I value highly, and recommend as a late-keeping and valuable variety. M. Jamin has probably not proved these excellent Pears raised by Mr. Huyshe, Victoria and Prince Consort, and he omits a Pear that has carried off the prize for high quality at the metropolitan shows, Knight's Monarch. I do not find that excellent late Pear, Beurré Rance, named; it is one that should be included in every collection; for late use it is the most valuable Pear I grow.

Beloele.

WILLIAM INGRAM.

Autumnal-tinted Vine Leaves.—I know of no leaves which become more richly tinted in autumn than these of certain varieties of Grape Vine, a houseful of different kinds of which presents at that season as interesting and diversified an appearance as a mixed plantation. The leaves of Barbarossa attain the finest of hues, which consist of golden-yellow, vivid reddish-scarlet, and deep green. In some the centre is yellow, belted with crimson and edged with green; in others these colours are reversed. These markings are not confined to decaying leaves, but also exist on fresh foliage, whose veins and tissues are full of sap. In some places leaves of this kind are sought after for garnishing; this variety of Vine is, therefore, alike useful in autumn for its delicious fruit and its strikingly pretty foliage. Old planted-out rods of the Black Alicante keep their leaves quite green up to the very last, when they become yellow and decay; but the leaves of young one-year old canes of this variety are exceedingly beautiful. Long before they are ripe they assume a bright red colour, charmingly suffused with yellow; these, like the leaves of the Barbarossa, are very useful and elegant for purposes of decoration. The foliage of Lady Downes becomes spotted, but not in a pretty way. Gros Colman has very peculiar leaves, the edges of which, about midsummer, become withered up as if scorched by fire or badly attacked with red spider, and by autumn they present a very withered appearance. This is the character of the variety, and when looking worst it is, nevertheless, in perfect health. West's St. Peter's, on the contrary, is a variety worth growing as a climber, on account of the beauty of its foliage alone, which early in autumn becomes bright scarlet, beautifully veined with green. Barbarossa, Alicante, and West's St. Peter's have all foliage of the most attractive description.—J. MUIR, *Clovenfords*.

Origin of remarkable Belgian Pears.—The Abbé Hardenpont of Mons, was the first of the race of Belgian fruit growers. In the last quarter of the last century, he obtained from seed the Beurré de Hardenpont, the Passe-Colmar, the Beurré Rance, and the Delices d'Hardenpont, some of which still hold places of the first rank in advanced Pomology. M. Van Mons, of Louvain, quickly followed, having between 1787 and 1854, raised 500 kinds of new Pears, several of which are of the highest class. M. Berent, between 1845 and 1854, produced within that decade no less than sixty new kinds; in 1828, he produced le Delice d'Flays, which is even finer than les Delices d'Hardenpont. The Society Van Mons, only produced eleven new Pears during the sixteen years of its existence, showing that individual perseverance is very generally more successful than combined efforts. M. Gathoge, of Liege, produced in 1852, Beurré Edouard Morren. In 1828, M. Magnery obtained from seed the Poire Renoz, a good and fertile summer kind; and M. Henrard, as early as 1840, introduced his Ben Chrétien and Vernois, said to have been received from France. M. Legepent, of the Commune of Charneux, produced in 1800, the celebrated Fondante d'Charneux. The Ben Chrétien Lamarche, was found in a convent garden of the province of Leige, where its origin was unknown.—From "Les Fruits Belges," by M. Gilbert.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Strawberries for a Keutish Garden: BEGINNER. The following will suit you:—Vicomtesse Hécart de Thury, Keens' Seedling, Rivers' Eliza, Sir J. Paxton, President, Mr. Radclyffe, Amateur, British Queen, Admiral Dundas, and Elton Pine.—J. B.

Cultivating Fruit Trees.—So great is the loss resulting from stunted and diseased growth, occasioned by neglected cultivation, that an intelligent cultivator gave it as his opinion that if nine-tenths of our orchards should be cut down, and the labour and cultivation which they receive be expended on the remaining tenth, more and better fruit would be raised.

Mulching Fruit Trees.—A correspondent of the *Horticulturalist* planted 150 trees in an orchard in very good but rather dry soil. All were planted with equal care, but a third of them were mulched, or the surface of the ground, when planted, covered with 6 inches of litter. Those thus treated all lived; but fifteen of those not mulched died in the hot dry weather. It is not stated that the soil was kept clean and mellow around them, which will often save the life of trees.

Pears and Apples for Cold Regions.—*Pears:* Seckel, Flemish Beauty, Giftard, Virgultien, Sheldon, Lawrence, Winter Nellis, on Pear stocks. *Louis Bonne* of Jersey, Tyson, Angouleme, Winkfield, Osmond's Summer, Glou Morceau, on Quince. *Apples:* Red Astrachan, Sops of Wine, Early Joe, Gravenstein, Oldenburgh, Porter, St. Lawrence, Fameuse, Ribston Pippin, Baldwin, Jonathan, Peck's Pleasant, Pomme Grise. The above, according to a trustworthy American fruit grower, are the best for very cold regions, and as such deserve noting by British growers.

Grafting the Peach.—This, in the Northern States of America, requires great skill for its successful performance, but at the south, where growth is so much more rapid, and other influences more favourable, it is comparatively easy. Mr. Robert Harwell, of Mobile, long known for his skill in fruit culture at that place, gave the following results of his practice:—I propagate all my Peaches by grafting, beginning in November or December, and if the stocks and grafts are good and the grafting well done, I do not lose over five in a hundred. I have my grafting done at the house, and plant the grafts like Cabbage plants. I formerly budded, but found it very troublesome, and have entirely abandoned it.

THE LIBRARY.

ISMAILIA.*

This is an interesting book, containing a graphic account of an expedition organised by Ismail Khedive, of Egypt, for the suppression of the slave trade in Central Africa. It is well illustrated with plans and excellent woodcuts, one of which we reproduce. It represents a scene which occurred in the journey up the White Nile, a river remarkable for the luxuriance of its aquatic vegetation, the margin of the water on both sides being elegantly fringed with long Grasses, while here and there occur clumps and masses of the Papyrus, readily distinguished by their umbrella-like plumes. In the open spaces a species of Lotus grows and flowers very luxuriantly. Many native trees and plants are incidentally mentioned throughout the work. "I had," says the author, "European vegetables of all kinds, and, having cleared and grubbed up a portion of the forest, we

ORANGE GROWING IN THE AZORES.

The islands of the Azores owe their wonderful fertility to the nature of their soil, which gives evident signs of an eruptive origin. That of St. Michael, which is the home of the celebrated Oranges, has evidently been in two islands, the interval between having been filled up by cinders and lava. Numbers of volcanic cones are found in this space, and streams of lava have poured the detritus over the rocky ground, which, when modified by the humidity of the sea, constitutes a vegetable earth of incomparable fruitfulness. This favoured spot is divided and sub-divided into enclosures, surrounded by high walls, and designated in the country by the name of "quintas." Here the Orange is cultivated, and the culture is described as follows in "Cassell's Magazine." Hundreds of thousands are yearly gathered, embarked, and transported to the London market. There is probably no district in the world where the culture produces so much in so small a space. The tree does not belong to the primitive flora of St. Michael. The precise time when it was introduced is unknown, but it was certainly soon after the discovery of the islands. Botanists believe it to belong to the eastern countries

Nile Vegetation.

quickly established gardens. The English quarter was particularly neat. The various plots were separated by fences, and the ground was under cultivation for about two acres, extending to the margin of the river. I did not build a house for myself, as we preferred our comfortable barge, which was moored alongside the garden, from the entrance of which a walk led to a couple of large shady Mimosas, that formed my public divan where all visitors were received. In a short time we had above ground Sweet Melons, Water Melons, Pumpkins, Cabbages, Tomatoes, Cauliflowers, Beetroot, Parsley, Lettuce, Celery, &c.; but all the Peas and Beans, and a very choice selection of Maize, that I had received from England, were destroyed during the voyage. Against my express orders the box had been hermetically sealed, and the vitality of the larger seeds was entirely gone." We can heartily recommend this work to all interested in the new world opened up to us by Livingstone, Stanley, Kirk, Baker, and other well-known explorers.

* "Ismailia," By Sir S. Baker, M.A., F.R.S. Two vols. London, Macmillan & Co.

of Asia, and admit that it was only brought to Europe in the fifteenth century. A hundred years after that it was largely cultivated at St. Michael's, at which time the flower, neglected in the present day, furnished to the distillers a large quantity of exquisite essence. The exportation of Oranges was not much developed until the middle of the last century, whilst the war and Continental blockade, which ruined other commerce, seemed rather to favour it. The close alliance which was then established between England and Portugal created commercial relations, and a market for an unlimited supply of the products of St. Michael. The culture of Oranges has thus very considerably increased during the last thirty years, and the manner of cultivation has much improved. In former days the plants were left unsheltered. They were planted at great distances from one another, thus forming magnificent trees, covering a large surface of ground, one of which would bear from 15,000 to 20,000 Oranges. A heavy stone was laid on the top of the trees, to force the branches in a lateral direction, and to keep a low level, so that the wind might not destroy them. This system has, however, been entirely abandoned, as the damage was so great during the fearful storms of winter blowing over the Atlantic. A tempestuous night sufficed to cover the ground with Oranges, and thus destroy a fine

harvest. On some occasions the trees were themselves uprooted, or torn to pieces; besides which, the delicate buds coming out in spring generally suffered much from the damp saline spray brought from the sea by the wind. The idea was then adopted of enclosing the trees in small plots, surrounded by trees; but it was soon discovered that the shadow prevented the growth and ripening of the fruit; and it was not until 1815 that the present system was finally adopted. The quintas are now squares of from 40 to 50 yards across, whilst stone walls, from 3 to 6 yards high, surround them. The strongest blasts are broken against these masses of thick basaltic blocks, the unhewn surfaces of which are mortared together. Within this rampart a hedge of the Faya tree is closely planted, and thus forms a green curtain several yards in height. After many attempts to discover the kind of tree which suited best for a shelter, this native of the island has been unanimously chosen. For many years the cultivators tried the *Pittosporum undulatum*, an elegant evergreen tree imported from Australia. The beauty of its leaves and the rapidity of its growth seduced the eye; but it exhausted the land, and interfered with the growth of the trees it was used to protect. The Laurel of the Canary Islands, and also that of India, possessed good foliage and quick growth, but their roots extended too far into the ground. The Faya, on the contrary, improves the land, as its dead leaves form an excellent manure. Not only does it leave the trees which are planted near it all the nourishing juices, but it is found that many other varieties, such as the Oak and Elm, thrive better near it than when planted alone. Near the sea, however, the *Pittosporum* is used, as it resists the dust and salt from the sea better than the Faya. During the time necessary for these trees to grow, the land is sown with a kind of Broom, which is destroyed after three or four years. Some cultivators think that the quality of the Orange has suffered from this protection, both air and sun being intercepted; but time is required to solve so difficult a problem, as well as a continuous series of observations. The ground of the plantations must be ploughed and tilled for four or five years. After that twice a year it undergoes a superficial ploughing. The Lupin is often sown and dug into the land with a hoe, to improve it. This plant plays a large part in the agriculture of the Azores. The volcanic soil spontaneously furnishes flint, salts of potash, and phosphates. If it contained azote, any additional manure would be unnecessary. This is exactly what the Lupin is so rich in at its maturity; thus it is pulled up and dug in to complete the natural richness. Then the ground will yield, without rest, two harvests in the year; and Melons, Cucumbers, and Pumpkins, which with us require special beds, prosper in the common soil. Every year the dead wood is cut out, and the shoots thinned; but, as a rule, the Orange tree is never pruned. In dry seasons it is well watered if the supply be near, and sufficient in quantity. The trees are planted in a quinconx, leaving between them a distance of 12 or 15 yards; and from the first year the cultivator looks for some fruit as a reward for his labours, though the tree does not enter into full bearing for ten years. Then, if it be healthy, and planted in good earth, it yields from 1,000 to 1,500 Oranges yearly. An old and vigorous tree, whose branches are long and well thinned, furnishes the immense harvest of 7,000 or 8,000. In those quintas which are too large, the medium does not exceed 600 fruits, whilst the smaller ones bear from 2,000 to 3,000, showing how much good shelter and care will do towards increasing the crop. There are six principal varieties of sweet Oranges cultivated in the Azores. The common one is of middle size, slightly acid, and very sweet-scented. The skin is thin, and adheres well to the fruit, becoming a little thicker towards the end of the season. The *Comprida* is more aromatic than the preceding one, and also more acid. This tree is rarely loaded with fruit. Under the name of the Silver Orange is designated a much smaller one, with very firm flesh, extremely fine skin, and a greenish-yellow colour. The *Selecta*, or choice Orange, is large, of first-rate flavour, little acidity, and of a deep yellow colour. It has scarcely any pips, and does not ripen until April, which gives it a higher value. The *Ombigo* is flatter, and sweet, whilst it furnishes the largest crop of all. Finally comes the *Mandarin*, which differs little from the same variety grown in Malta. The fruit, as a rule, enters into its maturity in October, but the best varieties are not gathered until January, the season terminating in May. The trees are increased in a curious way. The mode of propagation was derived from the Chinese, and has been much in use of late years. A branch, of the diameter of 4 or 5 inches, is chosen, around which is cut a circular incision. Around this, straw matting is wound in the shape of a funnel, and filled with beaten earth, from the 15th of May to the same day in June. Roots soon begin to push, and by the following winter it is provided with sufficient to support it when detached from the parent stem. The young plant thus obtained often bears fruit at the end of two or three years. Formerly grafting was employed, and is indeed still used;

but it is somewhat out of fashion, on account of the relative slowness with which trees "worked" by it come into bearing. It is, however, asserted that the trees to which it has been here applied give the best fruit, and last longer than the others. The gathering in of the fruit is carried on rapidly, and without difficulty. Notwithstanding the constant emigration going on from the islands to North and South America, labour is very cheap. The Oranges are gathered with care, and carried to the packing-shed by large companies of men, women, and children, who bear on their heads or shoulders heavy baskets loaded with the golden fruit, and run barefooted to the depôt. There each is separately wrapped in a dry Maize leaf, and put in the box. The shape of these boxes has been entirely changed of late years. Formerly they were very large, and held from 700 to 900 of the common variety. Thin flexible planks formed a convex covering, without any solidity, and containing in the lid almost as many Oranges as in the box itself. Those who have seen cases unpacked will remember this curious arrangement, which was explained by saying that the air circulated more fully between these planks than in a box properly constructed, and that this was essential to the preservation of the fruit; but really the custom arose from the wish to escape the tax imposed upon all exports, which only prescribed the dimensions of the lower part of the case. The growers were faithful to the letter, if not to the spirit, of the law, by making the right size, and then surmounting it with an enormous cover. Thus formed, they could not be packed on board ship with any exactness, and the Oranges were but too often crushed. There is now a better understanding with the Custom-house authorities, and the large cases have finally disappeared. They are now rectangular boxes, about a yard in length, and hold only half what the former ones did. They are divided into three compartments by solid partitions, and surrounded by bands of Chestnut wood. The expenses of gathering, carrying to the town, storing, packing, embarking, and paying the dues, including the case and Maize leaves, only amount to the small sum of half-a-crown a case. As for the price of a box of Oranges, that varies very considerably during the season, generally advancing much towards April and May, when it is double or triple. There is also a great difference between one year and another, the state of the season, speculation, and a number of other causes influencing the London market. Sometimes Oranges, when gathered, are sold in the full season at St. Michael's at 20s. the thousand, packing and transport being at the cost of the buyer; other years they have been sold at 7s. 6d. In 1840 the number of cases exported to England was only from 60,000 to 80,000; in 1850 it rose to 175,000 of the old cases; lately about 600,000 of the newly-sized cases are exported. Formerly sailing vessels alone were employed for the transport, but now about half are steamers. The charge for freight to London is between 7s. and 8s. the case, which, it is hoped, will be lowered. Steamboats engaged in this service make eight voyages to England from the 15th of November to the end of April; each carries about 5,000 cases. The application of this kind of navigation has been of immense service. The sea is so stormy during the winter on the shores of the Azores, that a sailing vessel only reached London with a large part of its cargo spoiled. During the last ten years at Ponta Delgada they have been working at a mole, within which the ships can shelter in bad weather; but it is only the steamboats that can get out to sea during a south-west wind, which, unfortunately, is the prevailing one. Sailing vessels, when laden, have been obliged to wait whole weeks, to the great detriment of their cargo, before a more temperate sky permitted of their departure. Before the mole was constructed many sad shipwrecks occurred. Whilst the vessel was loading, the captain watched the signs of a change in the weather with the utmost anxiety, often interrupting the work, and giving the signal for flight, for fear of being dashed on the reefs round the coast. Such events are scarcely thought of now; and the contingencies being so few in the trade, the expenses can be much more surely estimated.

Impurity in Coals a Plant Product.—According to analyses by many chemists (quoted by Professor Dana, in the last edition of his "Geology"), made on Lycopods, Ferns, Equiseta, Mosses, Coniferae, &c., there is in them an average quantity of silica and alumina, such that, if the plants were converted into coal, it would amount to 4 per cent. of the whole, and the whole ash would be 4.75. Many analyses of bituminous coal show but 3 per cent. of ash, and 4.5 is an average. Hence it follows:—(1) That the whole of the impurity in the best coals may have been derived from plants; (2) the amount of ash in plants was less than the average of modern species of the same tribes; (3) the winds and waters for long periods contributed almost no dust or detritus to the marshes. In that era of moist climate and universal forests there was hardly any chance for the winds to gather dust for transportation.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

ALTHOUGH the season is now past for floral display in the open air, yet as late as the 10th of the present month out-of-door gardens were by no means destitute of flowers. Aubrietias, Forget-me-nots, and Violets of different sorts were tolerably gay; the Christmas Rose was apparently preparing to unfold its blooms, and the Autumn Crocus, late-flowering Asters, *Anemone japonica*, and other late-flowering plants appeared loth to leave us. A rather severe frost, however, on the night of the 10th, followed by a considerable fall of snow on that of the 11th, gave a somewhat wintery aspect to outdoor beds and borders, checking considerably the progress of early-flowering plants, and closing for the season the career of late-flowering species. The Christmas Rose (*Helleborus niger*), with its improved variety *H. niger maximus*, are well worthy of extensive cultivation, flowering, as they do, at a time when outdoor flowers are scarce, and during a festive season when they are so much required and appreciated. With but little care or attention, these plants will continue to bloom throughout the entire winter should the weather prove moderately mild; and even during severe weather the protection of a few hand-glasses or a frame will generally ensure an abundance of fine, large, and pure white blooms from the beginning of December until the early part of March. Christmas Roses are of easy culture and by no means difficult to increase; early in spring, large roots or patches may be unceremoniously cut into moderately small pieces with a sharp spade, and planted out singly, where they will soon become well established plants, and will flower freely during the following and succeeding winters. When all fallen leaves have been cleared from lawns and similar places, it may, in some cases, be necessary to again pass the mowing machine or the scythe over the Grass; and if the principal gravel walks, or those in immediate connection with the flower garden or the residence, are found to be considerably soiled through decaying leaves or worm-casts, or where the surface may have become covered with Moss, a portion of the surface should be scraped off, and should be replaced with a thin coat of clean gravel, which will tend to give the whole an appearance of cheerfulness during the winter. Finish as soon as possible all transplanting or re-arranging of shrubs and young ornamental trees, and when this has been done shrubberies should be lightly dug over; and, in cases where hardy herbaceous plants of various sorts are grown in the foreground, such plants should be carefully lifted, reduced in size where necessary, re-arranged, and again planted; and all plants which may require it should have fresh soil supplied to them when re-planted. Such additions may be but seldom required in the case of strong-growing herbaceous plants; but they are essential to the successful culture of such plants as the *Aquilegia glandulosa*, Dianthus of various sorts, *Claotharas*, Pentstemons, and many of the finer varieties of perennial Phloxes and Violas. Clean and refreshen the surfaces of beds of choice Pansies, Polyanthus, and Pinks, and give Auriculas and other choice Alpine plants in pits and frames abundance of air whenever the weather is mild. Similar treatment should also be given to all well-rooted bedding plants, except such tender species as the *Alternanthera* and the *Coleus*, which must be wintered in a higher temperature. —P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

Push on planting while the weather is favourable. Pot a few half-standards for forcing; they prove useful for placing at the back of an early Vinery, or in other situations in which they may yield a few cut blooms. Roses planted on lawns and Grass-plots should be examined this month; remove the turf from a space 4 feet in diameter round the trees, take out the soil, carefully extirpate all suckers, and fill in with some good fresh loam and rotten dung. All Roses planted against trellises and trained over umbrella wires require a supply of fresh soil every other season, a mode of treatment under which they may be induced to live and bloom satisfactorily for many years. I have seen standard Roses thus nursed, over twenty years old, quite an ornament to the lawns on which they were growing. Watch plants starting into growth under glass, and if mildew shows itself dust with sulphur without a moment's delay.—H. G.

Indoor Fruit Department.

Vines.—Such pot Vines as were first introduced into heat will now be showing signs of vitality; the temperature, which up to this time will have averaged 55° at night, may now be raised, in mild weather, 5° during that time, and 10° more in the daytime. Do not damp them too freely overhead, unless the temperature is high enough to absorb the moisture, as, while we have few opportunities of admitting

fresh air, the atmosphere must not be allowed to get loaded with moisture. Place plants enough in heat to meet spring requirements. In some cases a dozen now and then is sufficient; while others, who grow Vines more extensively, need scores. Successive batches should be introduced into heat at intervals of six weeks; less than this often brings in two lots together. The early-started Vinery will now require the assistance of a little fire heat at night, but this may still, in a great measure, be dispensed with, by turning daily part of the fermenting material which rests on the inside border. Repeated turnings allow the heat to escape freely into the atmosphere, and a soft moist warmth is thus produced, which is far more desirable than fire heat. See that the water with which syringing is done is not colder than the temperature of the house in which it is used. In many early forcing houses a tank is placed in such a manner that the hot-water pipes pass through it; but, where no such convenience exists, when done syringing, watering-pots should always be filled and set on the hot-water pipes until again required. Strictly avoid allowing cold air to pass in in draughts through front ventilators; air-giving now, and, indeed, throughout the winter, must be confined to the top of the house. In houses in which Grapes are hanging do not keep the temperature higher at night with fire-heat than just what will keep out frost, and when there is no visible indication that the thermometer will fall to 32°, let the fires go out altogether. When heat is required to dry the house fires should be applied on a fine day, when the ventilators can be opened, in order that moisture may freely escape, and not at night when the house is closed, and when damp rises only to settle upon the berries.

Pines ripening too quickly for consumption, or requiring to be kept for any special purpose, after they are ripe, may be kept in very excellent condition for a month or six weeks, say in a room in which there is a temperature of about 40°. Both plant and fruit should be thus circumstanced unless where any valuable suckers are attached, and are likely to be sacrificed. In this case the fruit may be cut and hung up, crown downwards, in the same room, but, under all circumstances, it is best to cut the fruit, and remove the plant and fruit before they are quite ripe. Watering must now be done with great care; feel each ball with the hand to ascertain if it really needs water. Look over Queens which are resting, and unless they are next to being dust dry do not give them any water. When a very fine day occurs, airing Pineries should receive attention, just the reverse of that recommended for early Vineries. The front ventilators should, in this case be opened. This mode has the very desirable influence of preventing the plants and crowns from becoming overdrawn.—J. MUIR, *Clovenfords*.

Indoor Plant Department.

Keep Chrysanthemums, at present gay, well watered, and divested occasionally of all shoots that will make cuttings for next year's plants. Solanums, of the *Capsicastrum* section, should also now be very ornamental, especially those of the new hybrid kinds, the berries of which are larger and brighter than those of the common sort. Cyclamens coming into bloom should be kept near the glass in the warmer parts of greenhouses; they, however, enjoy a free circulation of air, which should always be maintained. Of Chinese Primulas, the farthest advanced should be brought into conservatories, and succeeding portions should be kept in frames. *Serico-graphis Ghiesbreghtii*, one of our most valuable winter plants, is now coming nicely into bloom, as is also *Libonia floribunda*, likewise an invaluable plant for winter decoration. Azaleas, Camellias, and Heaths should receive plenty of light, and be kept in a moderately moist condition. The earliest *Cinerarias* are now coming into bloom, and should be placed at the warmest corner of the conservatory for a week or so, after which they should be removed to a cooler position. *Cinerarias* and *Calceolarias* in frames should be shifted as they require more pot-room. If climbing plants, trained along rafters, in any way darken the house, they should be thinned or cut in. *Daturas*, *Erythras*, *Clerodendrons*, &c., cut over, should be placed where they can be kept dry throughout the winter. *Tropaeolum tricolorum* and *Jaratti* should receive frequent attention in the way of training, for, if allowed to grow for a week or more without inspection, the young shoots are apt to get broken. Japanese Lilies should be re-potted and placed in dry situations in greenhouses. Stoves should range from 60° to 65° at night, and from 70° to 75° during the day. The syringe should be dispensed with, but a humid atmosphere should be maintained by damping the paths and stages. Palms cannot, with impunity, withstand the effects of drought, and the same remark applies to *Misas*, Screw Pines, and other evergreen plants. Cycads, although they can bear dryness at the roots longer than most plants, are best kept a little moist. Ferns should be well watered but not syringed. All young ones should be re-potted as soon as they become fit for the operation. Such large Ferns as are re-potted should be placed in warm quarters to induce them to

strike root in the new soil more readily than they otherwise would do. Selaginellas should be divided and re-potted.

Orchids.

Many of these are now finely in flower, more especially some of the species and varieties of *Cypripedium*, *Odontoglossum*, *Oncidium*, *Phalaenopsis*, *Calanthes*, *Phajus*, and others. In the East Indian or warmest Orchid-house a night temperature of from 60° to 65° should be maintained, while in the intermediate house it should be 5° lower, and in the *Odontoglossum* or cool house 5° lower still; atmospheric humidity should be maintained in all these houses, but more especially in the warmest one, in which the plants also should be kept a little moist at the roots. The syringe should be entirely dispensed with now in Orchid-houses; such plants as are on slabs should be taken down when necessary and dipped in water; for, if the syringe were used for damping them where they hang, the drip resulting therefrom would be likely to rot the crowns of plants growing underneath. *Anacochili* still growing apace must be kept a little moist, though not so much so as hitherto. *Pleiones* that have finished flowering should be shaken out of their pots and re-potted into a mixture of loam, peat, Moss, and sand, and afterwards placed in a brisk temperature. *Calanthes* that have finished blooming should be stored away under stages or set on side shelves and kept pretty dry. *C. Veitchii* and the red and yellow-eyed varieties of *C. vestita* are now in great beauty. Newly imported Orchids should be spread out on tables, suspended by the roots, or potted amongst half-inch crocks alone, and submitted to atmospheric humidity only until they show renewed signs of life.—B.

Kitchen Garden.

Amongst some kinds of late Potatoes, there is a good deal of disease; Regents, although a very heavy crop, have suffered the most—in some instances to the extent of one-third of the crop; whilst Victorias and Red-skinned Flour-ball have generally escaped. The last I consider a very fine Potato for use after Christmas; rather too large and coarse, perhaps, for a gentleman's table, but in all other respects a thoroughly reliable variety in almost all kinds of soils. Potatoes pitted some time ago should be examined, and their condition ascertained with a view to their being sorted over if necessary. Early Potatoes of the Ashtop section, or any other favourite early kind, that may be required for forcing or early planting, should be placed in shallow trays or boxes, one layer in each box, with the crown upwards, and all growths except one strong shoot should be rubbed off. The boxes may be set in some cool place but where frost cannot enter, and where at least a fair amount of light can be obtained; under a greenhouse stage or in an orchard-house are places in which they keep well; or, failing these, a light loft or stable, where the frost can be kept out, will answer; but they are more likely to be frozen in a loft than on a ground floor. If not already done, take advantage of fine days to finish earthing up late Celery and Cardoons, as frost severe enough to injure young growth may now come at any time unexpectedly. Collect together all kinds of refuse from every available source with the view of having it charred by-and-by when the fruit trees are pruned, and the cuttings are gathered together to form a foundation for the heap. Out of such waste products large quantities of valuable manure may be obtained free from seeds of weeds or eggs of insects. Stir the soil amongst the earliest Cabbages, choosing a fine day for such work, and then earth them up—an operation which will tend to strengthen and protect them, and consequently hasten their growth. A bed of Shallots and also one of Garlic may now be made on a dry well-prepared piece of land, to which a dressing of burnt earth, soot, or lime has been applied; plant in rows 1 foot apart, and 6 inches between the bulbs. Unless, however, this has been proved in each particular locality to be the best season for planting them, a portion of the stock should be set aside for planting in February. It is also a good plan to procure a change of bulbs sometimes, or raise some from seeds, as almost everything has a tendency to deteriorate if grown continually upon the same kind of soil. Turn over heaps of manure, and prepare it for wheeling on the land when frost sets in. Mushroom-beds in the open air will now require careful management in order to maintain a regular temperature; if the coverings get saturated with wet they should be removed, and dry litter placed next the bed, and every means should be taken, by increasing its bulk, to keep the heat in the beds. Successional sowings of Mustard and Cress should be made in heat; French Beans in pots should be kept near the glass in a warm light house; as they advance in growth a small stick should be placed to each plant and the plant be neatly tied to it; and all plants in bearing should have frequent applications of liquid manure, and every pod picked off when fit for use to prevent the premature exhaustion of the plants.—E. HOBBS.

EASTWELL PARK, THE SEAT OF THE DUKE OF EDINBURGH.

THE *Standard* gives some account of this fine old park. It lies in that part of Kent where, according to Fuller, "health and wealth are reconciled to live together." There is a district of "health without wealth," these high Downs which form what is called the backbone of the county, and there is another of "wealth without health," the deep, rich, ague-haunted pasturages of the marshes along the Medway and the Swale, and about Romney in the south. But the Eastwell country, north of the Weald, and south of the barren Downs, almost justifies Drayton's encomium:

O, famous Kent,
What county hath this isle that can compare with thee?
That hath within thyself as much as thou canst wish,

Nor anything doth want that anywhere is good.

It is richly wooded, yet not too much so; and the great Oaks which makes the glory of the Weald flourish here on the green sand just as vigorously as in the Weald clay. There are, indeed, few nobler Oaks in the county and few more picturesque woodland glades than are to be found in the Park of Eastwell, which Defoe, in his "Journey through England," declares to be the finest he had ever seen. From a hill in the north-west corner, toward which the avenues called the "Star Walks" converge, there is a view across the county on either side; on the north, Sheerness and the Nore are seen beyond the heights of Challock Wood and the Forest of the Blean; on the south, the Channel is visible beyond Romney Marsh. The massy leafage of the Oak at this time, varied with all the russets and "sober gold" of late autumn, gives character to the greater part of the wide prospect, and marks how little the main features of the country have changed since Gregory the Great, writing to St. Augustine, desired that British timber might be sent to him at Rome for building the churches of St. Peter and St. Paul. Let us hope that none of the ancient Oaks of Eastwell have been felled for building any portion of the new work at the hall. "It has not been unusually observed," says the gossiping Aubrey, "that to cut Oak-wood is unfortunate," and it would seem that the Oaks of Eastwell are under the protection of more than usually powerful wood-nymphs. "I cannot omit," continues Aubrey, "taking notice of the great misfortunes in the family of the Earl of Winchelsea, who, at Eastwell, in Kent, felled down a most curious grove of Oaks, near his own noble seat, and gave the first blow with his own hands. Shortly after his countess died in her bed suddenly; and his eldest son, the Lord Maidstone, was killed at sea by a cannon-bullet." The connection of these misfortunes with the Oak-felling is somewhat arbitrary; but Aubrey supports his story by others not less edifying, and tells how "there was at Norwood one Oak that had Mistletoe, a timber tree, which was felled about 1657. Some persons cut this Mistletoe for apothecaries in London, and sold them a quantity for ten shillings each time, and left only one branch remaining for more to sprout out. One fell lame shortly after; soon after each of the others lost an eye; and he that felled the tree, though warned of these misfortunes of the other men, would notwithstanding adventure to do it, and shortly after broke his leg." If these warnings are not sufficient to strike the Oak-cutter with terror, let him remember the fate of Archbishop Islip, of Canterbury, who, it is recorded, "wasted more of the timber in the Weald of Kent" than any of his predecessors; and who, after falling from his horse in riding from Sevenoaks, was seized with paralysis at Mayfield, in the very hall which he had built, and under the oaken roof which had once been growing timber in the green depths of the Weald. But, whatever "curious groves" may have disappeared from Eastwell, there is no lack of great Oak trees in the park, many of which are sufficiently gnarled and ancient to have looked down on the "last of the Plantagenets" as he wandered beneath their shadow. This is a country of "wells"—the water-springs bursting forth abundantly from the green sand on the edge of the chalk. Eastwell lies just below the line of the ancient "Pilgrim's Way," the road which, keeping along the sides of the Downs, was followed by those coming from the southern coast who sought the shrine of St. Thomas at Canterbury. Stunted Yews and Oak trees mark its course, and the pilgrims who journeyed along it altered to pay their vows to such lesser shrines as they encountered on their way. Such was Charing, a little west of Eastwell, where, in the church, was a remarkable relic—the block on which John the Baptist was beheaded—brought into England by Richard I. Charing was a manor of the archbishops, and in their palace there, of which there are considerable remains, Henry VIII. was entertained on his way to the famous Field of the Cloth of Gold.

LOCUST TREES have been found to grow in forty years, 60 feet high, and 6 feet in circumference at a height of 3 feet from the ground. The wood toughens as the tree grows older.

THE ARBORETUM.

EFFECT OF LIGHTNING ON TREES.

At page 450 allusion is made to the peculiar effect which lightning produced on a tree in this locality last September. The tree in question is one of the large Elms (50 or 60 feet high), in the Avenue de Paris, and is situated about 100 yards from my dwelling. On its trunk there exists three distinct perpendicular and perfectly straight grooves, completely denuded of bark; the grooves are, some 5, some 7 to 8 centimetres in width; the rest of the bark is perfectly intact; two of the grooves are 25 centimetres apart; the other is on the opposite side at 80 centimetres from the former. One groove continues high up among the branches to near the summit; the others begin at the lowermost part of the branches, about 12 feet from the ground. The grooves end abruptly, and are cut square off at an inch or so from the surface of the soil. This latter peculiarity I account for in this way. Small basins have been formed at the foot of each tree, with an opening on the other side to receive rain-water, and drain the surface of the foot-path. Three loud thunder claps had preceded this particular thunderbolt, and a smart shower falling there might very probably, therefore, have been an inch or two of water in the basin, which led away the electric fluid as soon as it had touched its surface. None of the branches were either split, stripped of bark, or denuded of foliage, the latter remaining fresh and green throughout. A singular circumstance, and one which I can attribute to nothing else but to this same thunderbolt, is that in my garden, 100 yards off, a Judas tree was found next morning with three-fourths of its foliage entirely dried up, crisp, and brown, as if a flame of fire had passed through it. The bolt fell at 10 p.m., and a strong smell of hot iron filled the house. Although the day had been very hot and sultry, this tree could not have been affected by a sunstroke, for the south side remained perfectly green. A Black Mulberry 10 yards off had a great many leaves here and there burned quite crisp, the others and far greater number remaining perfectly green; nothing else was touched, not even a Panlownia, the branches of which touched and intermingled with the Judas tree. I was myself travelling down to Normandy that day; the wind was blowing a stiff gale all day, hot sultry like a Sirocco, and clouds of dust hurried over the plain, obscuring the sky; we had no rain, neither had any fallen on the coast when we reached it, nor did any fall there until the next day.

Versailles.

F. T. P.

WEeping BEECH.

THE accompanying illustration represents a Weeping Beech tree after it has acquired age, and become well furnished with branches profusely laden with pendulous spray. It is a peculiarity of most weeping trees not to show their full beauty of character until they have attained a considerable age. Who knows anything of a Weeping Beech, who has only seen a young specimen recently planted? Years must elapse before such trees exhibit the appearance represented by the accompanying woodcut; but when that condition has been attained they form, in ornamental grounds, a never-ending source of interest.

THE WILD VANILLA PLANT.

By Vanilla plant we do not refer to the Orchid which furnishes vanilla, but to a hardy North American plant, *Liatris odoratissima*, which, on account of a similarity of odour, has received that name. Most of the species of *Liatris* or Button-snakeroot, have a tuber-like root, and long straight stems, upon which the numerous flower-heads are crowded in a close spike. In *L. odoratissima*, the root-leaves are from 8 to 12 inches long by 2 or 3 broad; those of the stem very small. The stem divides above into a broad branching panicle of purple flowers, which make the plant an attractive one. A correspondent of the *American Agriculturist* has furnished the following account of the plant:—"The Wild Vanilla, or, as it is commonly called, Hound's Tongue, or Deer Tongue, grows abundantly on the edges of what are called 'bays,' i.e., low places in the Pine woods, which are partially covered with water and overgrown with Bays (a species of *Magnolia*), or on low swampy Pine woods in east and south Florida and in portions of lower Georgia. The fresh leaf has, when crushed, a greenish disagreeable odour, but when pulled from the plant and dried in the shade for a day or so, it becomes highly fragrant, having a smell resembling vanilla or Tonka Bean, and similar to the sweet-scented vernal Grass, but much stronger. This odour is developed

by some chemical change made in the leaf during the process of drying, whereby a peculiar principle known as Coumarine is formed. Coumarine is found abundantly in the Tonka Bean of commerce, but so abundant is it in the *Liatris*, that it is often found in large quantities on the upper portions of a mass of the semi-dried leaves. It is readily sublimed by a low degree of heat (150°), and the heat generated in these masses or bundles is sufficient to sublimate it on the upper or cooler layer. When found in this way, Coumarine is composed of snow-white needle-shaped

crystals, exceedingly fragrant—a leaf of the *Liatris* often being covered on its under side, and looking as though it had been out all night in cold, frosty weather. The dried leaves furnish an article of commerce, and one that is steadily growing in importance. It is gathered all through east and south Florida, principally on the St. John's River and its tributaries, and sold to the country store-keepers in exchange for goods; by these store-keepers it is sent to the balers and packers, by whom it is sent to New York for home use and exportation. Pilatka, on the St. John's River, is the head-quarters in this trade. One may often see seventy-five or 100 bales, of 200 lbs. each, lying on the wharves, awaiting shipment—one dealer at this place having an order to fill of 150,000 lbs. Adults can gather from 150 to 400 lbs. of the green leaves in a day; active boys and girls nearly as much. The green leaves are taken home and dried in the shade, and lose about 80 or 85 per cent.; they are when dried, sold at country stores for from 3 to 6 cents, per lb., yielding quite a good return for the labour. The packer bales and ships, and realises from 8 to 12½ cwt. per lb. The dried leaves are used to give a flavour to segars, snuff, and smoking tobacco. For segars, it is sufficient to place the leaves and segars in alternate layers in a box, and allow the whole to remain together for several days; for snuff, the leaves are dried ground and mixed; it is granulated or shedded up and mixed with smoking tobacco. A small quantity is sufficient to flavour a large mass of tobacco. The odour is given off much more intensely

A Weeping Beech. (From the *Bulletin d'Arboriculture*.)

on a damp day than on a dry one. Although large quantities of these leaves are consumed in our home factories, a much larger quantity is shipped to Germany and France direct, where it is rapidly growing in favour. It is quite probable that it will soon be an article used extensively in perfumery; and as it is known to keep 'the wicked moth away,' it will be in great demand for the purpose in the stead of the strong-smelling camphor and tobacco stems."

PLANTING TREES FOR LANDSCAPE EFFECT.

At a recent meeting of the Scottish Arboricultural Society a paper on this subject was read by Mr. Gorrie. Were the question, he said, merely whether grouping or mixed planting was most productive of landscape effect, the unanimous verdict would be in favour of judicious grouping, and that on all sizes of landed properties—from the 2 or 3 acre villa plot, where groups were necessarily restricted to a few specimens, to the large estate, where groups might form masses of ten, twenty, or hundreds of trees of the same or closely allied kinds of trees. But were grouping only to be deemed admissible on condition of its being equally profitable with mixed or promiscuous planting, he feared that its most strenuous advocates would fail in its defence, more especially were it required that its landscape effects should be maintained unimpaired by other kinds of nurses from the time that the young trees attained sufficient sizes for concealing the natural herbage of the ground surface. He then went on to discuss the merits of grouping of trees for landscape effect under the following heads:

1. *Soil and Situation.*—For choice of these a widely-extended knowledge of arboricultural requirements were needed, and a knowledge of the wind-resisting powers of different kinds of trees, in order that they might be arranged so that the stronger should shelter the weaker.

2. *The Form and Size of the Groups.*—The form of groups should be irregular, and without hard or harsh outlines, as exemplified on a large scale by the few native forests that are still left in this country.

3. *Grouping with the same and Allied Kinds of Trees.*—By far the most commendable mode of group planting was that of associating species with their varieties, and others belonging to the same or allied genera.

4. *Grouping with different Kinds.*—Trees widely different in their affinities, but having a resemblance to one another in size and form of their leaves, might be associated in groups. Mixture of kinds was, however, most commendable when they possessed some other marked characteristic in common, such as colour of foliage, bark, or habit of growth.

5. *Grouping with respect to Size, Colour, and Form of Leafage.*—In planting, as in painting, light and dark colours, imparted apparent nearness or distance when the trees were equally removed from the observer. One of the seemingly most difficult problems that the landscape gardener had to solve was that of making straight lines appear crooked, and stiff ones easy, but it could be successfully accomplished by attending to the grouping of variously-coloured trees.

6. *Park Belts, Clump Groups, and Solitary Trees.*—Belts and clump groups were usually planted with unsightly mixtures of over-crowded ordinary kinds of forest trees rising abruptly to full height from the fence enclosures. They should be rounded or sloped down so as to associate harmoniously with the surrounding turf, and this was secured by planting ornamental trees of diminishing stature and shrubbery underwood. Park belts and clumps were admirably adapted for grouping trees, and underwood and detached clumps were specially suited for grouping the different families apart.

7. *Avenues.*—These might either be straight or curved, and were generally associated with a roadway or a grassy ride. They might either be composed of two lines, all of one kind of tree, four lines of two kinds, or tribes of trees, or what might be termed the arboretum avenue, in either two or four rows, all of distinct sorts, grouped or brought together in families. The first, when intended to form a close Gothic arch-like covering, should be planted near to one another in line, and they might be as near to the roadway on each side as half its width. The second, or double avenue, should generally have the rows next to the roadway or drive of one kind, and the other two rows of a different kind, but full space should be allowed for the after development of every tree from the ground upwards, without touching one another, encroaching on the roadway, or concealing from it the trees in the back rows. A very usual and generally commendable practice was to have two corresponding rows deciduous and the other two evergreen. The third, or arboretum avenue, was better in four than in two rows, where sufficient space could be devoted to them, as they allowed of the dwarfier kinds being kept in front and the taller ones behind; and in both the second and third kinds of avenues the

back lines might be associated with openly-grouped underwood and shrubbery when adjoined by plantations or where concealment of or from the outside was intended.

After touching upon fences as an important item in landscape gardening, Mr. Gorrie concluded as follows:—Applying some of the preceding remarks to examples of avenue treatment near at hand, you will, on visiting Sir Walter Scott's Monument and the Edinburgh Meadows, have opportunities of estimating the arboricultural taste and skill of our city rulers. At the former you will see avenue trees selected with the utmost disregard to their adaptation to either soil or situation—the kind being the common or Wych Elm, one of the most capricious of ordinary forest trees—each with a few feet of stem surmounted by a besom-like head of numerous contending branches. At the Old Borough Loch, according to Mr. Maxwell, Mr. Hope, of Rankellor, commencing about 1722, "raised beautiful hedges and trees, made rich meadows and pleasant walks where gentlemen and ladies resorted." In Campbell's journey through North Britain in 1810, these avenues are described as "a Mall lamentably unlike St. James's, being shamefully-neglected places, where there was no longer pleasure in wandering among broken-down hedge-rows and unsightly trees"—a description highly applicable to their management up to the present time.

EVIDENCE AS TO THE BEST TIME FOR TRANS-PLANTING EVERGREENS.

THE best season for transplanting evergreens, although beginning to be more generally agreed upon than formerly, still remains a question on which opinions differ. With a view to its settlement, we some time ago solicited the opinions of some of our correspondents on the subject, and the following are the answers which they have supplied:

Mr. Barron, of the Elvaston Nurseries, Borrowash (than whom few men have had greater experience in transplanting), says, "Respecting the best time for moving Conifers and other evergreens, I may say, that during the last forty years, I have removed them with complete success nearly every day in the year. With machine-transplanted trees of large dimensions (from the extent of my operations), I have been obliged to take them in hand at any season, excepting during severe frost. From the nature of your inquiry, I imagine however, that you wish me to state the time I prefer. In my 'British Winter Garden,' published more than twenty years ago, I gave summer as the best time, and after another twenty years of extensive practice in most of the English counties, I still prefer the period when a tree is in an active state. When a tree or shrub is removed with a ball of earth suited to its size, and properly supplied with food, the plant goes on without any signs of removal. Should these conditions not be attended to, disappointment or entire failure may be expected."

Mr. James Brown, author of "The Forester," writing from Craig-mill Nurseries, Stirling, says, "As a rule, the best time for transplanting Conifers is when the sap of the plants begins to move, and when their buds begin to swell. This takes place between the beginning of April and the middle of May, according to the nature of the season and the character of the species. When carefully removed at the stage indicated, I have invariably had perfect success."

"From a long and varied experience," says Mr. Davison, of White Cross Nurseries, Hereford, "I have no hesitation in recommending early autumn as the best time for moving Conifers and other evergreens, choosing dull or moist weather for the operation. Take them up with care and plant them immediately; then secure them well, by means of stakes and ties, from wind-waving—an important point; and well water them; repeat the watering every other day for a week, and syringe over head two or three times. By this time, if the work has been well done, the trees will have made fresh roots. In a favourable season, I consider the latter end of September or early part of October (before the trees cease to grow) the best time; but this will, of course, vary with the season and the continuance of the time during which the sap flows. On no account should the attempt be made unless the soil is well moistened, either by means of rains or watering, as in dry soil the roots, on the careful preservation of which success depends, would probably be bruised or otherwise injured. These remarks apply to nearly all evergreens, Hollies perhaps excepted. I have succeeded best with Hollies in spring, just as the young shoot is beginning to push and form new leaves."

Mr. Richard Smith, of Worcester, states that "Conifers, and all kinds of evergreens, may be transplanted freely from the end of October till the end of April, and, if the weather be cloudy, both earlier and later. The safest time for removing large trees that have not been transplanted for some years is early in autumn, as soon as the tips of the young shoots have become firm, and while the roots are in action. The next best season is late in spring, just when

the buds have commenced growth, but there is always some risk of injury from a drying east wind: the sun, also, may be hot enough to damage newly removed trees. The very largest trees may be successfully transplanted, but their weight and size render removal a costly undertaking. For a tree that would require two or three men to lift it, it is better, if time can be afforded, to prepare it the season before, by digging a circular trench 18 inches or more apart from its stem, and then cutting back all the roots, so that they may throw out a quantity of fibres, which act as feeders, and also materially assist in holding the soil together while the tree is being transplanted, for, after all, the secret of success is to keep a good ball undisturbed."

"The best time for planting Conifers," says Mr. Anthony Waterer, of Knaphill, "is just as they commence to grow, and as soon after as the young growth is sufficiently ripened, say April and the latter part of September, if the weather is favourable, *i.e.*, showery; we usually move all ours in those months; but a well-managed plant in a nursery may be safely removed at almost any season except in the midst of its growth, when, of course, the young wood 'burns;' and in the case of a Conifer the leader is of importance."

Mr. McNab says, "With proper machinery at my command and plenty of water for after deluging, I can venture to transplant Conifers at all seasons. For ordinary Conifers I generally recommend the time when the species commence to push out their young growths. If done when in this condition, and plenty of water given immediately afterwards, I scarcely ever saw them fail, that is if transplanted with adherent balls of earth. When lifted without balls the chances of success are very difficult. During the years 1866-69 about 1,400 Coniferous plants were removed into the new Pinetum formed in the Edinburgh Botanic Garden; they varied from 2 to 18 feet in height at the time of removal. Some were transplanted during every month in the year, and, with trifling exceptions, all succeeded well. Shading, syringing, and keeping the surface of the ground round certain plants covered with short Grass had to be attended to during warm weather."

In a useful little book by Mr. Kelly* "On Transplanting Large Trees and Shrubs," we find the following:—"The time for this work is autumn and spring; these are, undoubtedly, the best seasons for transplanting, but any season will suit the good large ball for evergreens, and for deciduous plants any time except in the height of the growing season, or in some instances immediately before the bursting of the bud. The best time for evergreens is during the dry warm summer, when the soil is warm and moderately moist. We transplanted a number of large old evergreens during the dry summers of 1869 and 1870, and in every case with complete success, although the soil was as dry as it possibly could be, and all the water used for the plants had to be carted half a mile. If deciduous trees are transplanted immediately before the bursting of the buds, some of them, such as the Birch, will bleed much wherever a root may happen to be cut. It is, therefore, much better to wait until the leaves begin to unfold (if it cannot be done in autumn)."

Mr. Marnock, who has had much practice in moving trees of all kinds, has promised to give us a short article on the subject, in which he will detail his experiences in full. We may, however, say that his practice differs widely from what were considered the best times of moving a generation ago.

"No doubt," says a correspondent, "late in April or early in May, and September are the best seasons for moving evergreens, especially if the plants are of large size; but, for choice, I vote for early autumn, for the simple reason that the ground is warm and the weather moist. For all evergreen plants, my experience leads me to consider from March to Michaelmas preferable to the other half of the year; but, for deciduous things, the wood should be ripe and the leaves falling before removal. On the subject of pruning trees at the time of transplanting, it is never wise to do so except in cases of excessive mutilation of the roots or of an exceptionally dry season; then to foreshorten some of the grosser shoots will reduce the evaporating surface, and whatever does that is, until new feeders are formed, for the good of the plant. Generally, when the leaves of evergreens drop off the plant will survive; but, if they wither on the branch, then success is hopeless."

Mr. J. Bell, writing from Strathfieldsaye, says, "Conifers and large evergreens may be transplanted with success at all seasons, but I much prefer the months of September and October, as then the plant removed, at once produces an abundance of fresh roots, and consequently makes much finer growth the following season than if the planting is deferred till early spring, when the earth is much sodden. I must add that I never water a newly-transplanted tree, but take care that the ball is sufficiently moist before it is removed; and, if the soil in which it is to be planted is duly watered and turned over, plants of every description will strike root in it at once."

Messrs. Veitch "always find Coniferæ to do best when planted in

autumn, as soon as the wood is ripe, say September and October, the exact time, of course, depending on the season."

The Scarlet Barberry.—This is most suitable for planting in woods and preserves. It is a very rapid grower—making shoots 5 feet long in a season—bushy in habit, and bears quite a profusion of scarlet berries, which render it a most conspicuous object in a wood in September and October. But, though it will thrive almost anywhere, it does not bear profusely in all kinds of soil. In the woods about Drumlanrig, in Dumfriesshire, where the soil is heavy and damp, and the climate so humid that the trees are grey with Lichen in winter, the Barberry flourishes uncommonly well. It is planted pretty freely in the open spaces, and when I saw it last there, in September, the woods were fairly lit up with it, producing a most striking effect. On a dry soil it grows well, but the fruit is neither so abundant nor so brightly coloured as that at Drumlanrig. The fruit is used as a preserve, and, owing to its thickly-set spines, the plant makes a good hedge.—J. S. W.

Tree Planting.—Do not plant near your house any trees that will ultimately attain large dimensions, or the day will come when you or your successors will have to choose between cutting down handsome and favourite old specimens, or suffering from the gloom and moisture generated by their too close proximity to the house. Many a fine old mansion has been thus overshadowed, and the inmates have had to elect between unhealthy damp and shade on the one hand, and the uprooting of a venerable tree on the other. Equally avoid planting tall-growing trees, where, when they attain maturity, they will interfere with a fine prospect, or intercept the view of any beautiful object. When first planted, their ultimate magnitude is overlooked, but the planter must have an eye to the future. In planting masses of trees, not only size and shape, but also the colour of the foliage must be an element in determining the selection of the species to be planted. The lively light green leaves of deciduous trees in spring, and even their graceful spray in winter, wonderfully relieve the sombre foliage of Conifers and other evergreen trees. An admixture, too, of those species of which the leaves change colour and assume bright tints in autumn, afford delightful glimpses and lively effects amongst other trees. For instance, the Birch and Tulip tree turn yellow, the *Cryptomeria elegans* dark bronze, and the Red Oak displays large masses of bright scarlet. These and others producing similar effects should be freely interspersed among ornamental plantations. Trees with variegated leaves, or with pendulous branches, also afford striking contrasts of colour and form, but they should be introduced discreetly, as, when too abundant, they lose their charm, and rather pall upon the sight. Do not encourage Ivy or other creepers to grow on trees which you wish to keep healthy and long-lived. These parasites do best, and look best, on decaying objects, whether trees or ruins, to which they add grace and cause no injury. Label all your choice trees and shrubs, or at least one of each species. Even if their names be familiar to the owner, they may be new to many a visitor, to whom it will generally prove interesting to know the names, and, if possible, the native habitat of the plants he surveys.—*Heatherside Manual*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Propagating Laurels: J. S. W. H. Laurel cuttings may be put in now. Well-ripened young wood, with a heel of old wood, is to be preferred, but if the young wood is not of sufficient length, a portion of the last year's wood may be retained. Put in the cuttings in lines on a north border.

Thuja gigantea as a Hedge Screen.—I am laying out a new garden (about 3 acres, including kitchen garden and shrubberies) on a somewhat stiff clay, but on a southern slope where I have well drained. I am anxious to know whether, on such a soil, *Thuja gigantea* is likely to make a good hedge about 100 yards long to divide kitchen garden from terrace, and whether it will grow close and stand clipping?—A. C. R. [Yes, *Thuja gigantea*, commonly called T. Lobbi, makes a good hedge screen at Newstead and various other gardens with which we are acquainted.]

A Buried Forest.—The *East Anglian Daily Times* announces the discovery by Mr. J. E. Taylor, F.G.S., of a buried forest in the Orwell. The forest is represented by a layer of peat containing trunks, leaves, and fruits of the Oak, Elm, Hazel and Fir, among which lie remains of the Mammoth. A bed of fresh-water shells, containing species not now living in the Orwell, underlies the peat. Mr. Taylor remarks that this sub-marine forest was contemporaneous with others along the coast which existed previous to the depression separating England from the Continent.

Abies Menziesii.—Very hardy, and grows with extraordinary rapidity; in some cases 3 to 4 feet in a year. Timber excellent. In California it grows to the height of 70 to 90 feet, with corresponding girth. This tree ought to be planted extensively for forest purposes, and would yield a profitable return much sooner than almost any other, either Coniferous or deciduous tree. It needs only to be tried and appreciated.—A. MONGREDIEN. [Surely Mr. Mongredien, in his "Heatherside Manual," puts this tree very much too low. We have not seen it in its native state, but have seen specimens in England nearly as tall as the height he mentions. We had imagined it would attain 150 feet or more. Will some of our Californian readers kindly tell us?]]

* Allen, Stationers' Hall Court, Paternoster Row.

THE KITCHEN GARDEN.

FORCING SEAKALE.

SEAKALE may be had in perfection from November till May; and carefully cooked and served with melted butter, it is equal almost to Asparagus. It is also one of the easiest of all vegetables to cultivate. It must, however, be blanched as it grows, or it is uneatable. Once let colour into it, and no amount of after blanching will get the rank flavour out of it. From the time its buds start to the time the Kale is gathered, no ray of light should reach it. It will be as good grown in a dark place indoors, such as a kitchen closet or cellar as under pots, closely enveloped with fermenting dung, tan, or other heat-yielding substances outside. A deep sandy saline soil suits the cultivation of Seakale best; but it will also grow well in any common garden ground if not too retentive. Common clayey soils may speedily be modified to suit Seakale by the addition of cinder ashes or sand. Though, of course, pre-eminently a salt plant, it will also grow well and continue in health without it, though good cultivators give it a sprinkling several times during the growing season. The best time to raise Seakale from seed or offsets is March or April; the seeds may either be sown broadcast in beds or in drills, about 2 inches deep; cover or tread in at once and rake smoothly. A pint or a quart of seeds will raise plants enough for any garden. They soon germinate, and may be left in the seed-bed or drill for one season. In March following transplant the young plants into rows 2 feet apart and 15 inches crown from crown; or plant the crowns in threes, pretty closely together, at distances of 2 feet. Another and better mode is to plant double rows from 1 foot to 18 inches apart, placing the plants in the two rows alternately, and leaving from 3 to 5 feet spaces between these double lines. This arrangement is favourable to forcing on the ground, as two rows of pots can thus be placed near together and covered with fermenting material which should consist of leaves with a sprinkling of dung, to quicken the heat. The double rows also facilitate another method of forcing. This consists in digging out a trench in the centre of the intervening space, 2 feet or more in depth and 30 inches in width, placing the soil on the crowns of the Kale and filling up all round with fermenting leaves and dung. Through this covering the Kale grows white and tender, and the earth, if light, is not found to impair its flavour. Offsets, cuttings, either of root or top, speedily form good plants, each crown, with or without roots, becoming a plant. These should be planted in rows, in the mode and at the distances prescribed for yearling seedlings, or as follows:—Seedlings and young plants may be grown in rows 2 feet apart, and the plants only from 6 to 9 inches asunder in the rows. All they require is to be kept clear during the summer, and at the end of the first season's growth take up as many of such plants as are required, and place them thickly in pots or boxes. Place the roots and crowns in a dark place, in a temperature of 55° to 60°, or exclude the light by covering them over with a flower pot, pan, box, short board, or some opaque body, such as sand or light earth. In about three weeks or a month, Seakale, white as silver, and brittle almost as blown glass, may be gathered in this way. If a continuous supply is desired you have only to introduce plants in succession, and treat them in the same way, once a month, fortnight, or three weeks. If watered when first planted they will seldom need a second application. The plants will also produce a second cutting, equal in flavour, though not in size, to the first. As this has to be forced from dormant buds on the stems, and takes longer time to grow, it is not worth waiting for, especially as plants are so cheaply raised and prepared. F.

JERUSALEM ARTICHOKE IN MARKET GARDENS.

THESE are not much grown in market gardens in the neighbourhood of London, Mr. Poupart, of Mortlake, and Mr. Humphreys, of the Fulham Fields, being, perhaps, the largest growers of them in the districts alluded to. As this vegetable may be grown in almost any place, it is generally planted on gravelly pieces of ground that would be too dry for other crops. Knolls or mounds are usually cropped with it, and it is also grown along the sides of hedges, and in shady places. Mr. Poupart grows his stock of it on a very fine alluvial soil, open and somewhat dry in the summer, and the result is an abundant crop of fine tubers. After preparing the ground by manuring and digging or trenching it, the tubers are planted in February, in rows about 2 feet apart, like Potatoes, and are allowed to grow unchecked, and without being earthed up, till November. By this time they will be ripe and in good marketable condition. The stems, which are sometimes killed by the frost, are cut over close to the ground, and earth is spread over the tubers to exclude frost. The tubers are lifted for market as required, for it has been found that their flavour is better when treated in that respect like

Carrots and Parsnips, than when lifted and stored in pits. In February, all are, however, lifted, for if left longer they would be useless for culinary purposes; what are required for sets are then saved for that purpose, and the remainder sold. Although February is the common time for planting the Jerusalem Artichoke, it may be done at any time between November and March, using small medium-sized tubers for the purpose. F. W.

THE COLORADO POTATO BEETLE.

Our Potato fields are, happily, as yet, free from this beetle, which is at present so troublesome in some parts of America; in case, however, it should pay us a visit, we have thought it well to make our readers acquainted with its appearance in order that they may be able to detect its first outbreak. It appears that there is another insect, belonging to the same genus, which is often mistaken for the Colorado beetle. It is, however, easily distinguished from the genuine type, as the second and third stripes are always united behind, giving the appearance of a heavy black stripe, and the edges of all the stripes have but a single row of punctures; the legs also have a black spot in the middle of the thighs. This insect has been found feeding upon the Horse Nettle (*Solanum carolinense*), in South Carolina, and has been taken upon Potatoes and Egg plants in Alabama, and was particularly injurious to the latter. In the accompanying wood cut (for which we are indebted to the "Proceedings of the Department of Agriculture at Washington"), fig. 1 represents the true Potato beetle, *Doryphora decem-lineata*; fig. 3, the *Doryphora juncta*; and fig. 2 is an apparent cross between the

two, or a variety once found in the south, in which the heavy, thick black line of the *juncta* has a very fine yellowish line running partly through it longitudinally.

WHEN SHOULD A KITCHEN GARDEN BE MANURED?

THIS is a subject upon which considerable differences of opinion exist. Some advocate manure being got on and dug in through the autumn, others prefer the spring. It is a matter that requires to be looked at from two different points of view—the effect that the manure has upon the crop it is intended to benefit, and the effect the difference of time in applying it has upon the manure itself. So far as most vegetable crops are concerned, the more evenly the manure is spread through the whole body of the soil where the roots penetrate—the better it is for the plants that are to be fed by it. This will be evident to anyone acquainted with the action and requirements of vegetable life; and any crop so situated will make greater progress, and ultimately be more productive than a similar crop to which the same weight of manure has been given, but less evenly dispersed. The reason is obvious; the feeding roots from the time of their first emission, all through their extension through the soil, have always had their food supply regularly at hand without being compelled to traverse through portions of a poorer nature, and only at times come in contact with the manureal food supply, although there in larger quantities. This, as will be seen, refers to solid manure, for, in the case of strong, quick-growing plants, no system of manuring is so effective as applying it in a liquid state at the time and season when growth is most active. This will be evident to anyone who has studied Chinese husbandry, where by far the greater portions of their crops receive the manure in a liquid or semi-liquid state, the cultivated vegetation of the country being particularly suited to such treatment. But, apart from the effects of manure upon the different crops to which it is applied, there is another important consideration—economy in its use, and how it is affected by the times and seasons at which it is put in the land. This operation is one that should be ruled by the nature of the manure, and also the description of both surface and sub-soil of the land on which it is applied.

Strong, heavy clays soils have the power of most effectually absorbing or extracting from the water that percolates through them whatever ammonia is there held in suspense, as also of retaining, and forming what we may call a storehouse for this most important element in plant food, until absorbed by the feeding roots in the water which they suck up from the soil, which after its upward passage through the plant is excreted through the pores of the leaves by evaporation, leaving behind the ammonia with which it was charged to combine with the other elements present and necessary to build up the vegetable fabric. If, then, soil of this strong heavy description has the power of absorbing and retaining the manurial elements, and not allowing them to be washed by the rains through and away deep down into the sub-soil, or carried away through the drainage, real or artificial, and consequently out of the reach of, and lost to, the crops we want to benefit, the manure may be applied at any time through the autumn when the land is uncropped. But even where the surface soil is of this strong loamy character, it is necessary that it should be sufficient in depth, so that the rain water, charged with this plant food it so quickly extracts from the solid manure directly it comes in contact with it, may not pass through the upper or surface soil too quickly, and so carry off a portion of the ammonia. A great deal also depends upon the nature of the sub-soil. Where such happens to be of a loose sandy character, or gravel, unless the surface soil, however retentive, is some 2½ feet or more in thickness, manure for spring or summer crops should not be applied until near the time the crop is put into the ground, otherwise very serious waste must necessarily follow; if, on the other hand, the sub-soil is of a heavy clay nature, even if the surface soil is shallow, the manure may, without fear of loss, be put in the land at any time when it is clear. Sand has very little power to absorb ammonia water, in which it is held in suspense, running through it in almost the same condition in which it was applied; and, in the same proportion is light sandy soil unsuited to receive manure until as near as possible to the time when the crop will be in a condition to utilise it. All soils of a gravelly nature are in the like similarly unsuited for autumn manuring. The nature of the soil has also a good deal to do with the quantity of manure that should ever be applied at one time; strong deep loams may have very heavy dressings given through their ability to hold for a lengthened period whatever portion existed over and above the requirements of the crop that immediately succeeded the application; on the other hand, in the case of light soils, it is a waste of manure to give more than will be sufficient for the immediate crop. T. B.

Veitch's Self-protecting Cauliflower.—We have sent you a head of this Cauliflower which we have received from one of our growers in Yorkshire. We believe it will prove a valuable variety for use in November and the beginning of December, and, being so thoroughly protected by the foliage, it will withstand several degrees of frost. Subjoined are the dates of sowing the seed of this variety, Autumn Giant, and Walcheren, and the result:—Veitch's Self-protecting sown April 8th; Veitch's Autumn Giant sown April 18th; Walcheren sown April 29th. The result is that the two latter are off while the Protecting is only now coming in.—JAMES VEITCH & SON. [The specimen sent exhibited unusually luxuriant growth, the leaves being upwards of 3 feet in length, and some 11 inches in width, with wonderfully strong mid-ribs. The head, which was well protected, was white, about 8 inches in diameter, close and firm.]

Lime Kiln Heating.—Messrs. Thyne, of Glasgow, have adopted the Cowan system of heating with excellent results. The kiln employed is 12 feet in depth, and is filled to the top with alternate layers of coke and limestone, which may be burned quickly or slowly, as desired. About 2 feet from the surface is a ring boiler, and over the whole mass an ordinary saddle boiler, the two acting in concert. Connected with the boilers are a series of flow pipes and valves, through which the water, after being heated, passes to the pipes led into the hot-houses. If it is necessary to get hot water quickly, this may be effected by coke alone being used as fuel, while a diminished temperature is obtained by withdrawing the water through return pipes, with which the boilers are also fitted, and making it circulate in a waste cistern until it is again required in the hot-houses. In this way the kiln may be kept continually burning, and more or less heat used at pleasure. The apparatus in this case supplies 7,000 feet of 4-inch piping, and as regards cost, Messrs. Thyne are supplied with coke at 8s. a ton, and limestone at 10s. a ton, in both cases delivered for that sum at the nursery, while lime-shell brings 2½s. per ton. One ton of coke is sufficient to burn 3 tons of limestone, the product of which is 2 tons of lime-shell, so that every 38s. spent in raw material brings 18s. for the manufactured article, the profit

sufficing to pay cartage from the works and the wages of a man who looks after the kiln. In this way the heating of the hot-houses is effected without any expense, whereas formerly Messrs. Thyne paid not less than £300 a year in coal and wages.

THE HOUSEHOLD.

COLD VEGETABLES.

SERVANTS often waste vegetables, even at times when they are scarce and dear. Cold Greens, for instance, are frequently thrown away as not eatable. This is wasteful; they are as good as when first cooked if they are thrown into a saucepan of boiling water, or into a basin of boiling water, and covered for two minutes; then strain the water from them, and serve hot. Cabbage of all kinds, and Broccoli and Brussels Sprouts, Peas, &c., can be warmed in the same manner.

Spinach may be re-warmed in a basin in a hot oven two or three times over with great advantage to the flavour of that vegetable if a little more butter be added.

Parsnips, when dressed whole and cold, should be mashed with butter, milk, and salt, put into a small buttered basin, made hot in the oven, be turned out in a dome shape, and served hot; they are better in this way than in any other.

Carrots should be cut in round pieces half an inch thick, and warmed in butter sauce or thick gravy. Carrots are extremely useful to keep ready dressed for an emergency or need in cooking. Large Carrots should be scraped or pared, be put whole or cut, once across their length, into boiling water, with a bit of fat or dripping in it, and be boiled two hours, then served unsplit, but cut into as many pieces as may be liked. Afterwards, when they are cold, they may be cut into any shape for serving with ragouts or hashes, or split into narrow strips for soups, or grated for the same purpose, or for puddings. There are two things to be avoided in warming all these vegetables, they should not be warmed in a saucepan, nor touched with an iron spoon.

Potatoes, when whole and cold, may be dipped in melted bacon fat or dripping, have salt sprinkled over them, be well floured, and baked in the oven on a tin, and turned round when needful; or cut in slices, floured, and fried in boiling fat, drained on a wire-drainer, or on paper and served hot; or chopped finely, salted, and fried in a little hot bacon fat; or mashed and mixed with a little milk and butter, and be formed in buttered shapes, as in tea-cups or large egg-cups, then rubbed over with a bit of butter, be floured and browned in the oven or before the fire; or fried in batter, by cutting them into rather thick slices, beating up an egg with a tablespoonful of cold water, and a tablespoonful piled of flour, then dip each piece in and fry in boiling fat; or Greens dressed cold and then chopped, and fried with the Potatoes, also chopped; or Carrots dressed and cold, chopped finely, mixed with the finely-chopped Potatoes, and fried. Potatoes, when young and cold, can neither be mashed nor chopped, but they can be rolled in a little clarified butter, or bacon fat preferable, and browned over a clear fire on the gridiron; or young cold Potatoes may be warmed in boiling Parsley and butter, and with a dash of Lemon-juice over them.

Celery.—There is nothing more useful in a house than this. The outside will serve as flavouring for soup, and the hearts cooked for the table, or to be eaten with cheese. First of all, remove the outside leaves from the hearts, and trim the roots, not cut them off. Have two large pans of water, one of warm, the other of cold water; wash each outside stem of the Celery in warm water with a brush, and throw it into the cold water, also the hearts; and all gravel, insects, and dirt falls from the Celery at once; take all the outside pieces and pare away every faulty and discoloured bit; then split each piece in two, or three or four, and cut it crossways in very small bits, and put it in a pie-dish. The hearts of the Celery must be laid aside in water, and when a head or more is wanted it can be taken from the water and cut in proper shape to be served at table, but before it is put into the last water any discoloured bit must be cut from it. To the small Celery in the pie-dish add one or two large Turnips pared thin, then cut downwards from the head to the root in a dozen cuts, but not separating the Turnip; then turn the Turnip round in the hand and cut it the other way in a number of cuts; hold it on a plate and cut it across. The Turnip will now fall into many square pieces. A Carrot may be cut in the same way, and this mixture will last for a week to put into cold soup, stock, or broth, and well boiled, to give flavour to it. Thus there is thrift of time and thrift of vegetables, for it takes no longer to prepare this for the consumption of a week than it does for one day. Moreover, Celery thus prepared will keep good, crisp, and well-flavoured for a fortnight, oftentimes for a longer time.

THE ABBEY GARDEN, REDDITCH.

ABOUT the end of the last century it was more usual than it is now to meet with artificial ruins in connection with gardens; and those who have read, or can remember having seen the "Clandestine Marriage," will call to mind how Mr. Sterling, when showing Lord Ogby his grounds, complains that his ruins cost him many hundreds to keep in repair. At the present day artificial ruins are almost confined to "tea gardens" or other places to which the "working man" resorts "to spend a happy day." Indeed, such constructions, for many reasons, can never be pleasing to a well-educated mind; they are false in material, false in form, and false in position and use; and though Nature may clothe them ever so luxuriantly with Ivy, Wallflowers, and Mosses, she never hides their puerility or their deception. Over the real ruin she kindly throws her green mantle, hiding the wounds inflicted by man, and shielding it as far as is in her power from those of Time the destroyer; and where some venerable remnant of antiquity occurs in a garden, as at Margam and elsewhere, it is legitimate to use it as an ornamental feature, and to aid Nature to clothe it with vegetation. It does not, however, fall to the lot of every person to have *in situ* on his grounds such ancient remains, either ecclesiastical or baronial; and I confess that I do not approve of the removal of these into private gardens, or the transplanting of such monuments from the sites which they may have occupied for centuries, unless it be absolutely for their own preservation. In one case, however, such a removal took place under my own care and management, and in this, as the object of preservation was accomplished, and beauty and interest that would otherwise have been lost, were added to an easily accessible English garden, I do not consider that any offence was done either to propriety or good taste. The garden to which I allude is situated in the grounds of Captain Bartleet, at Redditch, in Worcestershire, and is known as the Abbey Garden, from its main features consisting of exhumed remains from the neighbouring (lost) abbey of Bordesley, in combination with such flowers, trees, and plants, as are usually found in connection with monastic ruins. Before describing the garden itself, however, it may be well, perhaps, to give a short account of the men to whose labours the agriculture and horticulture of the valley around Redditch owe much; and, but for whose settlement there in the middle ages, the present Abbey Garden would never have existed; and I do this because I believe that few are aware of the influences which at least one class of monks had upon the cultivation of the land. It was then in the troubled reign of King Stephen when the sword was seldom sheathed, and the trumpet was everywhere blown for wars, that there came to live in the Vale of Arrow a community of Cistercian monks, a religious order of men, who, leaving Learning and the Arts to others more ambitious than themselves, studied the peaceful occupation of cultivating the soil. No sooner had these monks of Bordesley settled in their new convent by the river-side than they began a number of works, many traces of which remain to the present day in the form of huge dams thrown across the valley, or raised in other places where it was desirable to erect water mills or to construct ponds for fish, or water fowl. They planted their orchard, Vineyard, and garden, and taught the church vassals the art of clearing, draining, and planting the soil; for it will be well to bear in mind that in those troublous times the abbey lands were the only places where cultivation of the soil could be peacefully and successfully carried out. Owing to the freedom which these monks enjoyed from the evils of war, and of that ambition which beset the more learned orders, the Cistercians and the hinds who gathered around their convents could devote their time to objects useful to man. Doubtless, it was the wars upon the Welsh marches which prevented the present fruit-growing county of Hereford from taking its due place in the middle ages, for we do not call to mind any passage in any old writer where it is celebrated for that which now calls forth the admiration of the stranger—in spring, when the orchards are silvered with blossoms, or in the autumn, when they are golden with fruit. In Robert of Gloucester's "Chronicle" the palm of fruit-bearing is given to Worcestershire.

In the county of Canterbury most fish is,
And most chase of wild beasts at Salisbury, I wis,
At London ships most, and wine at Winchester,
At Hertford sheep and oxen, and fruits at Worcester.

While the Vineyards of Gloucestershire produced a wine little inferior, in William of Malmsbury's estimation, to that of France, the characteristic fruit of Worcestershire was the Pear. The Black Warden from long ago has figured on the shield of that county; the Pear tree was the badge of the Worcester men at Agincourt, as it is now in 1874 that of the Worcestershire Rifle Volunteers; and a fine Pear tree, formerly growing in the Foregate of the "Faithful City," attracted the admiration and praise of Queen Elizabeth. Without doubt we owe many plants and fruits, not indigenous, to the monks, for the convents were the hotels and guest houses of the middle ages, and palmers and pilgrims brought thither the seeds of such plants as had excited their curiosity or their appetite in foreign parts, or which had grown in sacred soils. The Glastonbury Thorn was brought from Palestine, and asserted its foreign origin by blossoming at a season deemed miraculous in this country. From illuminated MSS. we should judge that the monks cultivated some flowers merely for their beauty; but the chief object of monastic gardening was to grow those plants and herbs which were useful as food or medicine, though of "vegetables," using the word in its domestic sense, there would be few varieties. Probably our English Strawberries owe their excellence to the pains taken by these ecclesiastics, and the Bishop of Ely, in the testimony of Shakespeare may be relied upon, had devoted some of his leisure time to the growing of them.

This garden, Sir Christopher Hatton's, and others in Holborn, were doubtless in high cultivation in Shakespeare's day; but, though these and monastic gardens generally have passed away, there yet remain drawings of some, as, for instance, of the gardens and Vineyards attached to Canterbury Cathedral, which show that great pains were taken to select proper sites, and to secure the proper irrigation of the land chosen. These remarks have been made merely to remind the reader that the monks were not, as is too commonly supposed, a class of men whose duties lay wholly in religious exercises. But now, in order to come at once to the subject of the present article, we must pass over a long lapse of years, during which time the Abbey of Bordesley, after the monks had been expelled, and the materials of their dwelling had been sold piecemeal, gradually disappeared from the face of the earth, until a few green mounds, and one or two decaying Pear trees alone marked the site of the building and orchard. It was in the year 1864 that Captain Bartleet was permitted, in order to verify some points in the "History of Bordesley Abbey," to make some excavations among the green mounds just mentioned. In the course of laying open these, a number of hewn and carved stones were found, as well as encaustic tiles of a wonderful variety of patterns. To bury these again would have been to hide their beauty and interest perhaps for ever, while to convert them into a rockery would have been to degrade and injure them. Captain Bartleet, therefore, resolved to make them the leading feature of an abbey garden. To accomplish this, a square, corresponding with that of the original cloister of the abbey, was marked out on the scale of 1 foot to the yard. It had two entrances, one to the north, just where a doorway was ascertained to have stood in the original building, and another on the west, and at these two entrances were placed the remains of doorways discovered in the excavations; the stones being cemented together with a cement coloured to give it the appearance of age. Along the line of the square, broken walls were constructed of hewn stone, and into these were built interesting pieces of carving; while where the supply of the hewn stone failed, Yew trees from the Arboretum at Worcester supplied the place, and continued the line of enclosure. In one part of the wall would be a broken window, in another the base of a pillar or a piece of shafting; and to the east was a little ruined chapel, constructed out of materials which furnished windows and arches, nook shafts and capitals of pilasters, the floor being laid with encaustic tiles more or less perfect. Amongst the stones Mosses were planted in such a manner as not to hide any of their peculiarities; whilst Ivy and creeping or trailing plants were trained up, or to hang

over, plain portions of the walls, but kept carefully cut away where their growth would injure or hide a capital or other piece of carving. Within the cloister, and at a distance of about 6 feet from the walls, ran four sunken walks parallel with them, thus leaving a square platform in the middle and four other platforms on the sides. All these were covered with turf, and little groups of carved stones were placed in various spots about them, while the base of one of the great pillars from the minster nave occupied the centre of the square platform. It will be seen that this arrangement of the stonework gave ample scope for the planting of Ferns, Ivies, and Mosses about the garden, in such a manner as to harmonise with the tone or feeling of the place. Not that the Abbey Garden is restricted to these, though they, with curious Grasses, Thorns, and "weeds" form the chief part of the "decorative" vegetation, for we may consider the Yew trees rather as part of the "construction." Among the Thorns is the curious *Crataegus tortuosa*, a plant whose pet aversion is a straight line. As this garden was constructed on part of the older one attached to The Shrubbery, several trees and plants of some size grow among the ruins, thus giving to the Abbey Garden an appearance of much greater age than it really possesses. J. M. WOODWARD.

THE WATER-SUPPLY FOR COUNTRY MANSIONS, GARDENS, &c.*

THERE are many very large establishments, such as hospitals, barracks, prisons, union workhouses, educational institutions, &c., situated in isolated positions, and in which large numbers of persons are lodged and maintained, where a good and abundant supply of water is of the greatest importance and necessity, both for consumption and as a protection against fire. In addition to these objects of first importance, I may enumerate others, such as the many purposes of ornament or pleasure, served by an ample water-supply, as well as its absolute necessity for the successful prosecution of horticultural pursuits, and its great value in cases where large numbers of cattle and horses are kept in situations where great labour would be necessary in pumping the supply or conveying it from a distance. The qualities of water vary very considerably. The softness of water is a quality much sought after. This property is found to vary according to the source from which it is obtained, some districts supplying soft water (which is the purest form), others affording hard water. Those waters which come from the chalk or limestone formation are invariably hard, varying generally from 16 to 20 degrees of hardness (Clark's scale), that is so many grains of carbonate of lime in a gallon. These, upon boiling, will leave in a short time a thick deposit, or fur, upon the inside of boilers, kettles, &c.; but by this process the water becomes softer in proportion to the lime precipitated. Waters from the green sand and new red sandstone formations are probably the purest and softest of any of the kinds which are drawn from the earth; but the softest, and those containing the least degree of hardness are those which are gathered from elevated and mountain countries, having 4 or 5 degrees of hardness only; but they usually contain inorganic substances, and are frequently tinted with the colour of the herbage or soil on the surface of the land from which it has been gathered. Except in appearance, however, this water is the best for clothes-washing, boiling, tea-making, brewing, &c.; while the hard and well-aerated waters are more sparkling, fresh, and agreeable to drink. This leads me to the subject of filtration. The materials generally used for filtering purposes are sand, and gravel, and animal charcoal. It has been found, however, by experiment, that the pores of the charcoal, although it absorbs organic matters for some time, will sooner or later become clogged, and will cease to arrest those matters; and not only does the charcoal cease to act, but it will return the matters which it at first absorbed. However, for small filters, where the material can be replaced or reburnt, it will answer the purpose. For filtering reservoirs, sand and gravel of various sizes have been found the best medium. The sand must not be too fine, lest it should become choked, and it must be freed from admixture with all ferruginous and other matters. In the supplies that we are here considering, it will rarely be necessary to provide filters in the reservoirs. It is worth while to mention a curious fact in connection with open reservoirs. It has been observed that, in shallow reservoirs, there has been a growth of confervæ, and, on the decay of this, animalcules have sprung into existence; but this has never occurred in reservoirs containing a depth of 15 to 20 feet of water, or where they have been covered and kept in the dark: it

is, therefore, necessary to bear this in mind when constructing service-reservoirs. In order to confine the operation within the smallest possible limits, the filter may be so contrived on the premises as to deal only with the water to be used for drinking, washing, brewing, &c.; while for stables, cattle, gardens, house-washing, closets, flushing sewers, and fire-service, the water may be left unfiltered. It will be necessary to have the tank or reservoir occasionally cleaned out; and it should, therefore, be constructed in two parts, so that one part can be cleaned while the other is full, and a continuous supply be thus ensured. Reservoirs or tanks should be left uncovered when they are in the open country and away from smoke, dust, leaves of trees, and other polluting sources; but, if near buildings, they should be covered, to keep these matters out, as water is very quickly impregnated by such, especially when shallow. As before stated, the greater the depth the less liability is there to this danger. There are probably few towns supplied with such good water as London; all that is taken from the Thames and the Lea being filtered, and we know that in both cases the sources are chalk and the strata both above and below that formation. As a rule, all the softest kinds of water are most injurious to and destroy iron more quickly than the harder water; but this is, in a great measure prevented by Dr. Angus Smith's composition for application as a lining to iron pipes, tanks, &c. Dr. Voelcker states that water which has been acted upon by lead is not so injurious as we have been led to suppose. The waters which act upon and dissolve lead are those which contain organic impurities, alkaline constituents, such as carbonate of soda and potash, and those in which carbonic acid is present. Fortunately, however, the lead may easily be got rid of. A small piece of zinc in the water will destroy the injurious effects, because zinc is more readily attacked than lead; also, it will be precipitated by the carbonic acid which will be absorbed by the water on exposure to the air. An ordinary filter will arrest the particles of lead. From the report of the Water Supply Commission, it appears that moderately hard water, the hardness of which is due to the presence of carbonate of lime, when used for drinking purposes is not injurious to health. Persons, however, who are accustomed to soft water, might be disagreeably affected by changing it for hard water, and *vice versa*; but those who are in the habit of using hard water of that quality are not injuriously affected by it. But, although there is no evidence to show that water which is hard, owing to the existence of sulphate of lime, is absolutely injurious, water of that quality of hardness is objectionable. The evidence proves that, for washing, soft water is far preferable to hard, and is also more economical.

Quantity of Water Required for a Country House and Gardens.

The next branch of the subject which we have to consider is the quantity of water which it may be necessary to provide for a mansion and all its belongings. The basis of this calculation is, that of the number of persons who compose an establishment, and are dependent upon and require an ample supply; and, in addition, a considerable allowance should be made for storing it, to meet contingencies such as fire, the lessening or total failure of springs or streams in long droughts, and other causes at those particular periods, as in summer, when larger demands are made upon the supply than in other times of the year. In an establishment such as that of a nobleman or gentleman in the country, the personal requirements may not be more than ten gallons per head of residents per day, but, for all other purposes, such as house-washing, also for horses, carriages, cattle, watering pleasure and vegetable gardens and roadways, fountains, cooking, brewing, clothes-washing, and several other purposes, ten additional gallons should be provided, making twenty gallons per head as the probable consumption of the establishment; and, in addition to this amount, there should be provided, in case of fire, a storage equal to three months' consumption, in the event of the supply failing in dry weather. It would not be safe, in the event of fire, to depend upon the pumping or other means of raising water, or gaining it by gravitation to check fire, as much time is lost in getting the pumps to work, and the quantity may not be sufficient, and the force inadequate to send it to the required height. In some situations, where farms and villages on an estate are situated at great elevations, and where water is difficult to procure, or probably not of good quality—and again, in the case of fire—it may be necessary that the storage for the mansion should allow by a slight increase of its capacity to be extended to those localities. Another want sometimes arises, and that is the supply of ponds for cattle in the fields in summer. For this a very small pipe would be needed. It may be found agreeable to form a skating-pond, which requires a very small quantity of water to keep it supplied.

Mode of Supply.

The modes of supplying water are by pumping, either by steam or water wheels, turbiues, horse-power, or by hydraulic rams, from

* From paper by Mr. R. B. Grantham, C.E., at the Royal Institute of British Architects.

wells or from reservoirs, rivers, or streams, at a lower level than the building to be supplied, and thus raising it, so as to command the highest roof of a mansion and its surrounding buildings. In certain situations it is possible to gather and collect water in a tank or reservoir at such an elevation that it may, by its own gravity, be conducted to the premises by iron pipes at constant pressure, so that all parts of the buildings, gardens, &c., may be supplied without the expense of pumping or lifting. The latter mode of supplying water is far preferable to all others. The next best is that of pumping, either by steam, horse, or water power, up to a reservoir constructed on elevated land, so as to command the mansion where the mansion and buildings are situated on high land, and no higher can be procured within a reasonable distance, a tower should be erected which may be made more or less ornamental, according to the character of the architecture of the mansion. Upon this a tank should be placed; but a tank of this description is always objectionable, and must be limited in size, owing to the great expense of construction and the difficulty of combining a pleasing appearance with a large capacity. Where there is high ground a reservoir may be adopted, which may be constructed of brickwork or concrete, and puddled. The increased cost to attain size is not the same in proportion as in the case of a tower. Even the length of piping from the source of supply to the reservoir, and thence to the buildings, should not weigh against the adoption of the reservoirs built on high ground.

Details of Service and Water Supply.

I now wish to call your attention to a short description of a case of water supply which has been successfully carried out, and which affords an illustration of what is necessary in a fire service. The case referred to is one which I have lately completed at Somerley, the seat of the Earl of Normanton, in Hampshire. It was at first proposed to erect a water-wheel on the river Avon, and pump the water from that river to cisterns on the top of the house. This was afterwards abandoned in favour of pumping by steam from a stream on the north side of the house, the engine being further employed in sawing the timber of the estate, for repairs, &c. By attaching a homestead, the engine could be made to work the chaff-cutting, thrashing, and other machines, when not engaged in pumping. This plan was adopted, but the homestead was not built. Some springs of excellent water—soft, clear, and free from pollution—were found issuing from the sand and gravel, with occasional beds of clay, which compose the hills running north and south through the estate, and bordering the valley of the Avon. These contain a large body of water, forming, as it were, a natural reservoir. Their waters were collected in a service-tank at a high level, from whence the water descended to a pumping well near the engine. This well was constructed near the stream before alluded to, in which a dam was placed to keep up the water, so, that if necessary, the stream of water could let into the well. This water is of good quality, but rising on a moor in peat soil, is discoloured, and contains inorganic matter; the engine is of twelve-horse power, and drives a large circular saw for cutting up native timber, which, at times absorbs all its power. The water is raised up a rising main of 3 inches in diameter for 1,452 yards, to where it meets the 6-inch main, by which it is continued to a reservoir on Somerley Heath, a distance of 1,178 yards, altogether 2,630 yards, equal to $\frac{1}{2}$ mile, at an elevation above the engine of 110 feet. The reservoir, built of concrete, on the highest ground that could be found within a reasonable distance of the mansion, is open, in a clear atmosphere, so that the water is well aerated and kept fresh. It is 10 feet deep, 60 feet square at the water line, and contains 150,000 gallons. The engine generally pumps from two and a half to four hours a day (according to the consumption at the mansion) at the rate of fifty gallons per minute, which is much more than is required. The height of the water in the reservoir is indicated in the engine-house by means of Bourdon's Pressure Gauge, so, that the engineman can at all times see whether the water is falling, and when it is necessary that he should pump. From the reservoir to the mansion the distance is nearly one mile and a half, and the water is conveyed to it by a 6-inch main. The house has recently been raised one story higher and enlarged, with a conservatory, extensive terraces, with fountains, carriage-drives, and additional garden space, and all laid out with very great taste and elegance. The bottom of the reservoir is about 15 feet above the tops of the roofs, or the surface of the water is 25 feet above the roofs. The whole of the pipes are of cast iron, well jointed and lined with Dr. Angus Smith's composition, which prevents the corrosion of the iron by this kind of water. On its way to the mansion from the reservoir, it supplies the flower and kitchen gardens, the stabling and laundries. There are stop-cocks to shut the water off, if necessary, for repairs or additions to the pipes, taps, &c. The sizes of the various pipes are also given. Outside the mansion the positions of the hydrants are all indicated upon the walls near or opposite to them. Stand-cocks can be fastened in the hydrants,

and to them the lengths of hose are screwed on. The pressure in the pipes is sufficient to throw jets of water from these hydrants over and upon the roof of the mansion and gallery. Within the house the pipes are laid along passages, corridors, and under the drawing-room and saloon to the interior, under the picture-gallery, at both ends of which are hydrants immediately under trap-doors in the floor with hose, wrenches, and spanners ready at the shortest notice to turn the water on, and it can by these means be directed to every part of the gallery. The water is also raised by upright pipes to every floor of the house, and stand-cocks and hose are placed in recesses in the walls readily accessible and at such intervals that two lengths of hose from different stand-cocks can always reach and discharge into every room in the house. There are also large cisterns in the roof for supplying the closets and the warm-water apparatus, &c., all over the house. The working pressure on the mains at the house in this case is about 39lb. per square inch, which causes a sufficient discharge through the nozzle of the hose if worked only from the engine, but, if worked from the reservoir, several jets could be worked at the same time. The cost of the whole service of pipes and the reservoir, but exclusive of the engine, which exerts power for pumping about 4-horse power, was about £2,000, and the annual cost does not exceed £10. The amount of property which is protected is very considerable, comprising the building and furniture, and the gallery which contains a very valuable collection of paintings, statuary, &c. I may conclude by remarking, that unless proper attention is paid to the sources of supply being protected from pollution, the reservoirs, pipes, taps, pumps, &c., kept in working order, all the care expended in designing and carrying out the works may be abortive, and they may become a source of loss and disappointment, and even of positive annoyance and injury. Careful supervision and frequent exercise of all parts of a fire service are essential, and it should be practised say once a month, and a mechanic, such as a carpenter or smith, should be trained to work the system, making himself acquainted with all its details, and with the premises, so that he might be able to superintend the service, make slight repairs, &c. Such a person could probably also attend to the drainage and such like matters of the whole of the premises. Most serious consequences have resulted from the want of a practised organisation, even with every appliance at hand, and experience proves what confusion and alarm prevail on the sudden outbreak of fire, when all concerned are generally tumbling one over another, forgetful of everything but self-preservation. This is quite natural, and can only be counteracted by the confidence which will result from the existence of an effective and well-ordered fire service, under the control of a person capable of directing its use to the best advantage. Protection from frost was secured by laying the pipes at a depth of from 2 to 3 feet below the surface.

Stoke Newington and Hackney Chrysanthemum Show, Nov. 17th and 18th.—This was an excellent exhibition, both cut blooms and plants in pots being much above the average. Of the former, excellent stands came from Messrs. Sanderson, Smith, and Berry. Among plants in pots were some fine standards and pyramids, and also some well-bloomed specimens of other kinds, especially a collection from Mr. Rainbow, to which a silver cup was awarded. Some extra fine specimen plants were likewise shown by Mr. Drain, Mr. Holmes, Mr. Butler, and Messrs. Dixon. Of new Chrysanthemums there were but few. Six new fringed Pompons were shown by Messrs. E. G. Henderson, viz.—*M. Ulrich*, purple, with white tips; *Ernst Henry*, pink, very full flower; *Marc Aureli*, orange and red; *Le Parnasse*, bright puce, yellow tipped; *Lucerne*, orange and brown; and *Denticulatum*, light rose, with yellow eye; these are new forms, which will prove useful for bouquets. The same firm also exhibited three new Pompons, one of which, *Fabiola*, having a pale lilac flower of fair form, received a first-class certificate; the other two, *Aurore*, a bright orange, and *Cendrillon*, a very fine rosy-lilac, of the *Troevna* type, were also very good. A promising large-petalled yellow seedling flower was shown by Mr. A. Carey, *Isle Terrace*, Guernsey. A new sport, called *Primrose Darulet*, was also shown, but not in good condition. A very nice dinner-table decoration was put up by Mrs. Butters, composed of medium-sized flowers of Chrysanthemums, Grasses, Ferns, and scarlet Geraniums, the whole nicely finished off with *Epiphyllum*. Some nice bouquets were shown by Mr. Smith, Kingsland Floral Hall, likewise some good fruits, the whole being relieved by some well-grown plants of Palms, Ficus, Ferns, *Dracaenas*, and *Araucarias*.

OBITUARY.

It is with regret that we announce the death of Mrs. Hooker, of Kew, which happened on the 13th inst., in the forty-ninth year of her age. Mrs. Hooker was a daughter of the late Professor Henslow, of Cambridge, and the wife of the distinguished President of the Royal Society, and Director of Kew Gardens. Mrs. Hooker translated *Le Maout and Decaisne's "Traité Générale de Botanique,"* which was edited by her husband; and we are sure that all who know Dr. Hooker will sympathise with him in his bereavement.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

RECENT ROSES.

By S. REYNOLDS HOLE.

ON Saturday, November 14th, while not a few of his mates were drinking away their wages and their health, a working man, from one of the foundries in Nottingham, set forth afoot for Mr. Merryweather's nurseries, fourteen miles away, at Southwell, purchased half-a-dozen Rose trees, and walked home again. I call that man a florist; I admire him more than Mr. Stanton or his bicycle, or Dick Turpin riding to York. I rejoice to think what happiness he will have in his tiny garden upon the hills by Nottingham when once more it is the time of Roses; and I know that hundreds who read THE GARDEN will sympathise with my hero worship. Are they not, many of them, at this very season showing signs of a like enthusiasm? Do we not see at all stations, and upon every carrier's cart, long packages deftly cased in matting or in straw, tightly bound with tarred twine or twisted osier, on their way to gladden Rose-loving eyes in cottage and grange, in parsonage and hall? For whenever in this month the weather is genial is the best time for planting Rose trees; and having spoken of those varieties among our older favourites, which I would most advise the young rosarian to plant, I go on, in fulfilment of my promise, to speak of recent introductions. Just reminding the amateur that Etienne Levet and Francois Michelon were not only the best Roses of their year (1872), but that they are of such superior beauty as to claim a place in every collection, I will pass on to those candidates which have subsequently sought election into the senate-house of Senateur Vaisse. First, I must compliment my friend, Mr. George Paul, of Cheshunt, upon the quiet, unpretentious manner in which he has introduced two of his children into the Rose world. We gardeners, it is well known, are the fondest of fathers. We don't go quite mad, like the French, and dance with joy round a fourth-rate seedling, crying, "ravissante, charmante, séduisante, tip-topissante," &c., but we lose much of our solemn British reticence, and not a little of our strict ideas of veracity, upon the birth of a novelty. Comparatively speaking, the raiser of Cheshunt Hybrid and of my namesake, Reynolds Hole, has displayed a marvellous modesty—nay, he has almost treated his offsprings as rough masters teach their pupils to swim—throwing them in to the water, and bidding them get ashore as they can. They have come to the surface, and acquitted themselves nobly. I can commend Cheshunt Hybrid (its name must have killed it if it had not been blessed with a robust constitution) as an excellent garden Rose, yielding an abundance of ruddy well-shaped flowers; and, as for Reynolds Hole, every friend who came near was taken to see it in September last, when, for many days, it was, to my intense delight, the best Rose I had in my garden. It is remarkably rich and striking in colour, all aglow with crimson tints. In habit it shows "notes of fatherhood" and of resemblance to Duke of Edinburgh, its parent, and has much similarity to myself, in the abnormal longitude of its limbs. Other rosarians, whom I trust, including "D. of Deal," have written to me, after seeing the Cheshunt Roses, to congratulate me upon the compliment which has been paid, and I feel sure that, when my synonym is established, acclimatised, and known, he will have that which I shall most heartily envy him, the smiling welcome of those who love the Rose. Two Duchesses of Edinburgh, too distinct in their complexion and form to suggest a rivalry, meet us next as we turn the pages of our new "Book of Beauty." The Hybrid Perpetual sent out by Mr. Bennett, of the Manor Farm Nursery, Stapleford, Salisbury, is a noble Rose, with the free healthy growth and leafage of Madame Boll, and the large, fresh, blushing bloom of Marguerite de St. Amand. The Tea-scented Rose from Messrs. Veitch, of Chelsea, is more adapted for the conservatory, drawing-room, and bouquet. There is no other member of its family at all

like it in brilliancy of colour—a vivid cherry-red; and it promises to be as generous in the quantity, as it is refined in the quality, of its flowers. Mr. Charles Turner, of Slough, has favoured me with blooms of some seedling Roses, which he purposes to send out in June next, and which encourage me to hope, more confidently than I have hoped heretofore, that we may at last succeed in raising Roses in England as abundantly and as satisfactorily as they succeed in France. I have not seen better wood or foliage, or more perfect Roses than Royal Standard and Miss Hassard. The Rev. J. B. Camm, and J. S. Mill had suffered too much in the journey for me to realise their merits, but the ruins were beautiful. There was also a Rose called William Gater (after one of the best rosarians that ever potted or budded a Rose), which ought to be, and is to be, a favourite. I have not had the pleasure of seeing Mr. William Paul's Queen of Waltham and Star of Waltham. From his description they must be worthy sisters of that Beauty of Waltham, whom we all admire, and will make a trio to vie with the Three Graces, not in cricket, but in contour. While I heartily wish the raiser this success, admiring his enterprise, and highly appreciating the benefits which he has conferred upon horticulture, not only as to Roses and Pelargoniums, but as concerns those beautiful ornamental trees, which are so striking in our landscapes, but have been so sadly neglected, I must, at the same time, expostulate with Mr. W. Paul upon statements which he has published, and which have been repeated by his son, to the prejudice of his brethren who grow Roses for sale, to the effect that Rose trees sent out by nurserymen who exhibit are weakened and exhausted by excessive growth, and will fail in consequence to please the purchaser. I not only dispute, but I deny, these statements. I affirm from experience, and have proved that which I say, that no better Rose trees can be procured than those which are supplied by Mr. George Paul, of Cheshunt, Mr. Cant, of Colchester, Mr. Cranston, of Hereford, Mr. Turner, of Slough, Mr. Keynes, of Salisbury, and other exhibitors. You may obtain (I am still writing from practical proof) equally good trees from other Rose merchants—such as Messrs. Wood, of Maresfield, Smith, of Worcester, Lane, of Berkhamstead, and fifty others, who do not show—but *not better*. If you remove fat young cattle from a luxuriant pasture, and turn them into a stubble field, an exposition of ribs will attend this manoeuvre; and if you transplant well-grown and well-fed Rose trees from good soil to bad, they will supply entertainment for green fly, mildew, and fungus, but not for you. So long as the wood is ripened (and this depends not on the seller but on the sun), the more there is of it the better, and to assert that, because show Roses have been cut from it, therefore all future flowers will be failures, is about as accurate as to suggest that those pullets which have taken prizes at the poultry show, are thenceforth incapacitated from laying eggs! I am hopeful that our French friends have sent us this year some good new Roses, but they indulge, as I have said, in such rhapsodies and ecstasies over their new born babes, that you can no more accept their estimates than I could endorse the valuation of two mothers whom I once heard appraising a baby, which one of them held in her arms—"Bless its little 'art," said the mother, "its worth a million a minit," and her companion promptly and earnestly responded, "Aye, tu." We feel inclined to apply to our southern brethren the Horatian precept,

Segnius irritant animos demissa per aures
Quam quæ sunt oculis subjecta fidelibus.

i.e., to translate freely, "We're much obliged to you for your descriptive catalogues, but we should prefer a peep at the Roses." With these fond papas a squint is, as Charles Matthews terms it, a "pleasing obliquity"—warts are beauty-spots, and red hair a warm chesnut. I have bought, notwithstanding, and advise others to buy, Captain Christy, which carries the name of one earnest rosarian, and the praise of another, Mr. George Paul, who first saw and admired it at Lyons. It is sent out by Lacharme, and is of the Eugenie Verdier type. Etienne Dupuy, I selected, partly from Levet's recommendation, partly from a sentimental association, weak and illogical I must allow, with the Etienne Levet, which has proved so precious. Jamain's Madame Bernutz has been well spoken of; and I have heard from all who have seen, that Madame Louise Leveque is a real

acquisition, and probably the best Rose of its year. It is raised from Jules Margottin, by Leveque; and the fact that it bears his surname is much in its favour. It has been pronounced to be a strong-growing Madame Furtado, and that sounds in my ears to be the description of a perfect Rose. Madame Marie Finger, raised by Rambaud, but sent out by Lacharme, obtained a first-class certificate at the Lyons Exhibition, June 19, 1873, and must, therefore, be a desirable Rose; and Madame Marguerite Jamain (like Madame Louise Leveque) would not have been honoured with the parental name if it were not seen to add new lustre to it. Miller Hayes I have annexed, not only because Eugène Verdier extols it, but because I have heard from others also that it is a worthy son of its father, Charles Lefebvre. I only hope that Pauline Talabot may justify the comparison with Dupuy Jamain, which has been made by a champion connoisseur, for I have had no more beautiful Rose in my garden (except La France, which, all through this season has here held pre-eminence) this autumn than Dupuy Jamain. I have only to add Thomas Mills, which I believe to be a first-rate Rose; but I have a presentiment that next summer will reveal to us other acquisitions, which are not included in my list, among the Roses of 1874.

SWEET-SCENTED PLANTS AND FLOWERS FOR WINTER DECORATION.

WHERE plants are grown largely for indoor decoration fragrant shrubs and flowers are generally in great demand, especially in winter, and amongst those most useful at that season is the common *Heliotrope*, cuttings of which, struck in the spring and grown on liberally in a pit or frame, fully exposed to light and air during summer, make robust and bushy little plants by the following winter, and flower freely if placed in a sunny position indoors. It is almost needless to state that such cuttings should be pinched once or twice during the earlier stages of their growth. *Mignonette*, too, as everybody knows, is invaluable during winter, and should be largely grown either for use in pots or in the shape of cut bloom. With many it does not succeed; but growers of it for the London market manage it simply enough. Their practice is to sow it in July in 48-sized pots filled with light, rich, sandy soil, thinning out the seedlings to four or five in each pot, and to grow them on in turf pits or canvas-covered frames as recommended for *Heliotropes*. The frames are only covered during very wet or hot sunny weather. The seedlings are stopped once, an operation which causes them to grow dwarf and bushy; and, if they show any inclination to flower too early the buds are removed. Thousands of plants of *Mignonette* are brought into Covent Garden Market every year treated in this manner, and all of them meet with a ready sale. Late *Mignonette* for cutting may be obtained by sowing seed in July on a warm south border, in a sheltered position, such as may be found in front of Vineries and plant-stoves, where it may remain until it flowers. I saw a fine row of it in full flower on the 3rd inst., and if the weather keeps favourable, flowering spikes may be cut from it up to Christmas. The large flowered *Jasmine* (*Jasminum grandiflorum*), one of the most deliciously fragrant of all winter-flowering shrubs, may be grown for winter use in pots (a plan adopted by Mr. Barron, at Chiswick), or, if cut flowers in quantity only are required, it is best to plant out a few strong specimens of it, and to train them along the back wall of a sunny stove or warm greenhouse. Mr. Wills, who employs it largely in the composition of choice bouquets, plants it out and trains it up the rafters of a warm plant-house, having a southern aspect, a position in which it succeeds well and flowers freely. Tea Roses, which are universal favourites, flower best when planted out in strong rich loamy compost, and when trained up rafters or pillars in a warm sunny greenhouse or conservatory. Market growers plant them out in little partly-sunk span-roofed structures, and train them over the roof; thus treated, and pruned in rather closely early in autumn, a plentiful crop of buds and flowers is obtained throughout the winter and spring. During the growth of Tea Roses, the syringe must be freely used to keep down green fly, and a few sprinklings of sulphur on the pipes will be found to check attacks of red spider.

Gardenias are universal favourites, and their culture is by no means difficult, all they require being plenty of heat and moisture, and abundance of light. Many object to grow Gardenias on account of their being almost invariably infested with mealy bug or scale; where, however, a large demand for their flowers exists, it is an excellent plan to devote a small heated span-roof house to their culture, and to train *Stephanotis* over the roof. Sponging, syringing, and a liberal use of insecticides will keep down insect pests; and the flowers of both Gardenias and *Stephanotis* are unsurpassed for purity and sweetness. Many market gardeners plant out their Gardenias in beds of loam and peat, while others grow them in pots. They do equally well either way, and the immense number of flowers which can be cut from a small house containing a dozen or two large plants of Gardenias is astonishing. Mr. Denning, gardener to Lord Londesborough, at Norbiton, who has a small house devoted to large plants of the double-blossomed variety of Florida, is now cutting blooms at the rate of 200 a week, with a prospect of even obtaining more from the same plants as the winter season advances. One of the best points about the Gardenia is that its flowers open one or two at a time, and a succession is thus obtained. Another fragrant plant not nearly so often met with in cultivation as it deserves to be, is the double-flowered *Tabernaemontana coronaria*. By some this is liked even better than the Gardenia, and it succeeds perfectly under precisely the same treatment. Its flowers are smaller and better shaped than those of *Gardenia Florida*, and the segments are beautifully crisped. A few plants of *G. citriodora* should be grown for the sake of its sweetly-perfumed orange-like blossoms, which are borne freely in the axils of the leaves on old plants. Among Violets, which are everybody's favourites, the best for general culture are the double and single Neapolitan. These may be readily propagated by means of offsets, or cuttings taken off in March and grown on liberally through the summer in pots. Many fail with Violets through neglecting them in dry weather. The single variety does well planted out on a mild hot-bed in a sunny frame—a position from which fine crops of flowers may be obtained; care must, however, be taken not to over-water, and they require covering up during cold frosty nights. A few plants of what is called the Lemon-scented *Verbena* (*Aloysia citriodora*) will be found useful; as will also *Myrtles*, both small and large-leaved. The Stag's-horn and Lemon-scented *Pelargoniums* are invaluable for winter use, and deserve to be grown in quantity. Tree Carnations and *Cyclamens* are likewise well worth attention; the latter are admirable for furnishing, and the Carnations yield the best of all flowers for bouquets and button-holes. B.

The Chanterelles.—A pretty group of Fungi, and readily recognised, are the Chanterelles. About a dozen are natives of our island. Three of these we have commonly in our woods at Hovingham, the edible Chanterelle (*Cantharellus cibarius*), the false Chanterelle (*C. aurantiacus*), and the trumpet Chanterelle (*C. tubæformis*). This group differs from the *Agarics* proper in being furnished with prominent veins on the underside of the pileus, instead of gills. These veins frequently anastomose, and they contain the spores of reproduction. Smaller intermediate veins may be noticed on the Hymenophore. The true Chanterelle is readily distinguished from the false by its aspect. The cap in the true is fleshy, and of a bright yellow, and the stem solid, whereas in the false Chanterelle the cap is thinner and downy, and the stem becomes hollow with age. Moreover, the fine Apricot-like smell of the eatable Chanterelle is sufficient evidence of its identity. Both grow with us under Oaks, but a mere glance is enough to distinguish the true from the false and unwholesome species. The Trumpet Chanterelle is greyish-black in colour. The normal form is like a Cornucopia, but we have in this country an aberrant kind, often met with, in which the pileus is simply umbilicate. It is named *lutescens*, and the two often grow together. The last named species may be found even in November, on mossy banks in woods, and is, doubtless, often passed by as an *Agaric*, probably an *Omphalia*.—PETER INCHBALD, *Hovingham Lodge, York*.

Plant Evaporation.—So great is the evaporation of water from plants, as stated by Mr. Lawes, that a plant of Barley of 172 days growth, in which it had acquired 119 grains of dry organic matter and 46 grains of dry mineral matter, had converted into vapour not less than 17 pounds of water.

NOTES OF THE WEEK.

— DR. WOODMAN writes to us from Exeter to say that the common Aspen (*Populus tremula*) is becoming scarce. He has endeavoured to obtain it from several of our principal nurserymen, but without success.

— BOTANISTS will be pleased to learn that the plants of Gay's Herbarium, presented to the national collection at Kew by Dr. Hooker, are now nearly all incorporated and available for use. This collection is extremely rich in European species.

— MR. THOMAS HOGG, writing from Japan to his brother, states that he has found there a new shrubby *Spiraea* with long racemes of white fragrant flowers, which, in his opinion, will be a decided acquisition to our list of hardy shrubs. He had thus far found but one plant, though he entertained the hope of finding others, or of obtaining seeds.

— ONE of our Swedish contemporaries states that the centenary of the introduction of Potatoes into Europe is approaching. It was towards the close of 1774 that Parmentier first succeeded in producing home-grown roots in France. It seems characteristic of the madness for festivals that just now distinguishes the northern races of Europe, that our Swedish friend suggests the propriety of getting up a great Potato Jubilee, more especially as the introduction of Potatoes into Europe is generally attributed to Sir Walter Raleigh.

— LORD NAPIER's report on military gardening in India states that the regimental gardens in many cases satisfactorily answer the purposes for which they were instituted, and that they not only supply very considerable quantities of vegetables to the commissariat for issue to the troops, but also serve as a pleasant lounge for the men and their families. The largely-increased number of men who now occupy themselves in gardening affords satisfactory evidence of the great interest which has been taken in company gardens during the past year. The only drawback to the success of the garden has been bad seed, but that is to be more carefully looked to.

— AT a late meeting of the Scientific Committee of the Royal Horticultural Society, Dr. Gilbert contributed, on the part of Mr. Lawes, a note on the occurrence of Fungi in the various plots devoted to experiments with different manures on permanent meadow-land at Rothamstead. The general conclusion appeared to be that Fungi flourished best where the development of Grasses was the least, and where the limited growth of these was due to a deficient supply for their requirements of nitrogen or of potash, or of both. The dry substance of Fungi appears to consist of from one-quarter to one-third of albuminoids, yet, as in the case of the highly nitrogenous leguminous crops, direct nitrogenous manures, such as ammonia salts or sodium nitrate, do not seem to be specially favorable to their growth. The dry substance of Fungi contains eight to ten per cent. of ash, of which eighty per cent. is potassium phosphate. Yet the greatest development of Fungi was on plots on which, measured by the requirements of Grasses, potash was relatively deficient. Dr. Voelcker stated that fairy rings occurred on poor pastures, and that the best mode of extirpating them consisted in the application of nitrogenous manures. Mr. Renny thought that rank-growing Grass was not nearly so favourable for the growth of Fungi as old pasture or common.

— WE are pleased to find that Mr. Cutler's long and faithful services, in the capacity of secretary to the Gardeners' Royal Benevolent Institution, are about to receive substantial recognition in the shape of a testimonial. When Mr. Cutler first joined the institution, thirty-two years ago, there were only two pensioners on the list, and the annual subscriptions were extremely limited in amount. By his indefatigable exertions the institution has been brought into its present prosperous condition, the annual subscriptions now amounting to the sum of £750, and the number of pensioners having been gradually increased to sixty-eight. In addition to this very large measure of relief afforded by the important increase in the annual subscriptions, Mr. Cutler has been eminently successful in inducing noblemen and gentlemen of influence to take such an interest in the institution that the funded property now amounts to the highly satisfactory sum of £10,000, affording to all the subscribers a sure guarantee that the purposes for which the institution was founded will be faithfully maintained and carried out in their integrity. The successive committees of the institution have always recognised that its advancing prosperity must be mainly attributed to the untiring energy of the secretary. With the view of giving expression in some tangible form to the wide-spread appreciation of these services, it has been determined to present Mr. Cutler with a suitable testimonial, and for the carrying out of this object a committee has been formed, who invite subscriptions from all who are interested in the work of the institution. Any sum not exceeding two guineas (to which the subscription is limited) will be received, it being well understood that the committee desire particularly to obtain as

numerous a body of subscribers as possible. Subscriptions may be paid either to Mr. Burnell, 79, Southwark Street, treasurer of the fund, or to Mr. Taylor (Webber & Co.), Covent Garden Market.

— WE have received from Mr. F. C. le Feuvre, Oak Walk, Jersey, a photograph of a remarkable Benrre Clairgeau Pear tree, which is growing against a wall at the Vineries, St. Laurence, Jersey. The tree is 10 feet high and 7 feet wide, and it produced this year thirty-five Pears, which weighed collectively 56½ lbs. The fruit, which is well brought out in the photograph, seems to have been borne at regular distances apart all over the tree.

— FURTHER investigations prove that the submerged forest, discovered in the Orwell, extends three miles down the river. The upper part of the peat-bed is filled with remains of forest trees, while the lower portions abound with aquatic plants, as if the place had once been a marsh. The bed of peat in which the remains are discovered is 7 feet in thickness, beneath which is the soil on which the forest grew, and finally the chalk.

— AT a late meeting of the Scottish Arboricultural Society, the chairman gave a brief report of the proceedings of the committee appointed to investigate the influence of trees on rainfall and climate at Carnwath, Lanarkshire. Mr. Buchan explained the situation of the experimental station as a forest of 62 acres, with a knoll in the interior on which the instruments were set, and at a distance of 320 yards a knoll on the outside of the wood, free from trees, on which a similar set of instruments was placed in almost identical positions to those on the interior knoll. The observations were made twice a day, with intelligence, care, and accuracy, and gave as a general result that during the spring and early summer months the air in the inside of woods was warmer and moister than that on the outside, while in the fall of the year it was colder and damper.

— THE groves of Rose trees and the flower farms of Morocco are said by a recent traveller to exceed in extent and value those of Damascus, or even those of the Valley of Mexico. The general climate of the country is very favourable to this kind of culture. Swept alternately by the breezes of the Atlantic and the Mediterranean, and tempered by the snows of the Atlas ranges, the degree of heat in Morocco is much lower than in Algeria; while the soil is exceedingly fertile. To the Date Palm and to Orange and Lemon trees the climate appears to be especially suited, the Dates of Tadilat having been famous even from Roman times. The Orange plantations are of great extent in various parts of the country, while Olives and Almonds are also staples exported in large quantities. Seeing that this fertile land, lying within five days' steam of London, produces so much vegetable wealth under the most barbarous cultivation, it appears extraordinary that European enterprise does not, in such a climate, seek profitable employment for its over-abundant capital, in its application to the development of such vast resources, so close at hand, instead of going so far afield as Australia or America.

— THE following prizes are offered by the Pelargonium Society, and will be competed for at South Kensington on July 21st, 1875:—Class 1. Twelve distinct varieties of Zonal Pelargoniums, "florists' class," in pots of 8 inches in diameter. (Open.) First prize, £8; second, £5.—Class 2. Twelve distinct varieties of Zonal Pelargoniums, "decorative class," in pots of 8 inches in diameter. (Open.) First prize, £8; second, £5.—Class 3. Thirty distinct varieties of Zonal Pelargoniums, "irrespective of class," in pots not exceeding 6 inches in diameter. (Open.) First prize, £6; second, £4. Note. The varieties to be shown in the above classes are to be of the flowering section—not those with variegated leaves.—Class 4, designated "florists' class," is intended to include only those varieties which have finely-shaped flowers, according to the florists' model. Class 2 is intended for profuse-flowering, showy varieties, otherwise known as Hybrid Nosegays.—Class 4. Six ornamental Cape Pelargoniums, dissimilar. (Open.) First prize, £3; second, £2.—Class 5. Best Hybrid Pelargonium, of distinct character. (Open.) First prize, £2; second, £1.—Class 6. Twenty-four Pelargoniums, cut blooms, single trusses, dissimilar. (Open.) First prize, £2; second, £1.—Class 7. Twelve Pelargoniums, cut blooms, single trusses, dissimilar. (Amateurs.) First prize, £2; second, £1. Note.—The judges may in their discretion, and subject to the approval of the committee, award a prize to any exhibit worthy of particular notice, which may not be provided for in the schedule. They may also withhold any of the above prizes if the exhibit be not of sufficient merit.—*Conditions of competition*—It is imperative that every variety exhibited shall have conspicuously appended to it, its own name, together with that of the raiser, such names to be either printed or distinctly written on a card. The "Chiswick standard" to be adopted in regulating the size of the pots—that is, "8-inch pots" measure 8 inches across and 8 inches deep inside, at a point 1 inch below the top edge; 6-inch pots in like manner measure 6 inches deep and 6 inches wide inside, at an inch below the edge.

THE KITCHEN GARDEN.

THE BEST VARIETIES OF CELERY.

AN admirable opportunity for observing and comparing the growth and character of different kinds of Celeries was afforded the other day at South Kensington, where prizes offered for the best three sticks of any white kind, and the same number of any red kind, brought together thirty lots, in which there was considerable variety. From Messrs. Veitch & Sons came a large collection of excellent examples, and from the Society's gardens forty-five so-called kinds were exhibited, but the differences between many of them were indeed minute. Celeries differ materially in colour, in habit of growth, in solidity—both of leaf-stalk and of the entire plant—in flavour and crispness of eating, and, finally, though not least, in good keeping qualities; the latter consisting of capacity to resist wet and frost and lateness in starting to seed. As a rule the red Celeries are thought to possess these latter qualities to a larger extent than white sorts, but that is not the case with all red kinds. Some prefer the flavour of coloured Celeries, while others like the colour of the red kinds, which, when blanched, are usually of a delicate pink hue, and, when neatly garnished with fresh green Parsley, they have a pleasing appearance on the dinner-table. White Celeries are usually considered to be the earliest; and are, therefore, invariably grown for the first crop. Some kinds are undoubtedly earlier than others, but much more depends on the period at which the seed is sown and the after culture, than on the early qualities of any particular variety. Probably there are no vegetables of which fewer sorts are grown in any one garden than Celery; a couple of kinds, one good white and one good red, generally being enough; but it is a matter of no little moment to be certain that these sorts are really good, solid, crisp, and well flavoured. It may be accepted, as a rule without exception, that any kind which, when liberally grown, has firm and solid leaf-stalks, will be certain to be crisp and of good flavour. In hollow-stemmed sorts the leaf-stalks are flat and oftentimes split; with good solid kinds the stems have a rounded shape, and each stalk overlaps and seems to grip the one beneath as in a vice. When blanched, the plants come out clean and sound, and invariably look well. Much, however, depends upon habit of growth, as some kinds are spreading, whilst others are upright, the centre of the plant being well protected. Celeries that have a sprawling habit of growth never turn out good; but upright growing kinds usually do. Moreover, they are easier to handle in earthing up, and it is only those who perform this operation who can fully understand the difference between the two habits of growth, as upon the manner in which earthing up is performed depends much of the after value of the crop. Earthing up should always be done on dry days, and gradually, special care being taken that only well pulverised soil is permitted to come in immediate contact with the plant, and this should be carefully pressed around it with the hand before the final earthing up is given, as, the firmer the soil the less will be the moisture around the plant. With the ordinary routine of Celery cultivation, however, most persons are familiar. Seed should be sown in March, in shallow pans or boxes, and placed in a gentle heat. When the young seedlings are 3 inches in height, they should be pricked out into other boxes filled with rich soil, or into a frame, the soil of which contains a large proportion of well-rotted manure, and these, again, when about 6 inches in height and strong, should be transplanted carefully, with good balls, to permanent quarters in properly prepared trenches. It is a rather too common practice to make the trenches so deep that the plants are compelled to grow in the sub-soil. The trenches should be marked out 5 feet apart; the top spit should be put on one side, and a spit of the sub-soil taken out and put on the other; the top spit should then be returned to the trench, and with it not less than 1 inches of strong rotten manure, which should be well incorporated with the soil with a fork. If this is carefully done before planting much more satisfactory results will be obtained than if the sub-soil were allowed to remain on the trench. The after-culture should consist of liberal waterings, and, as the plants increase in size, an occasional soaking

with manure-water might be given, but it is possible to produce a too-luxuriant growth at the expense of quality. Gradual and careful earthing up completes the process of cultivation. From the large number of Celeries grown at Chiswick it would be extremely difficult to make a selection of the best kinds without the possession before-hand of some knowledge of them. In the case of the sorts shown for competition the judges cut each stick through with a knife, and thus their qualities were at once apparent. The Chiswick collection was not thus operated upon, and, therefore, in looking over the different kinds, one had to judge more by feeling and appearance than by any other tests. Among red kinds none equalled for colour and compactness of growth the Leicester Red—a kind that is identical with Major Clarke's Red, and is probably the most compact of the coloured kinds. Very fine and firm were the samples of Sulham Prize Pink, and Carter's Incomparable Crimson, both distinct kinds, tall in growth and robust in habit. Another good-looking kind was the Manchester Red, of which there were several synonyms. Among whites the best and only true dwarf kind was the dwarf Incomparable White, commonly known also as Sandringham White. This is compact, firm, crisp, and keeps well. Next in height and quality came Veitch's Silver White, a good firm variety; the best of the tall kinds being Wright's White Grove and Seymour's Solid White. It is well worthy of note, that in the competition for Red Celeries the shortest Leicester Red was placed first, and that amongst whites the dwarfiest, namely, Sandringham White, was both first and second. A. D.

French Beans.—Is there more than one French Bean called Canadian Wonder? Mr. Gilbert (p. 385), strongly recommends this kind for forcing in pots (I expect that is the general way in which French Beans are forced), and after reading his description of it I was induced to try it in a frame on a bed of leaves, a way in which I have grown early crops for years; not having convenience for pots, I either sow in the frame or transplant from a pan early in March. The Canadian Wonder was planted in the frame and grew robustly, but bore no crop, or at least next to none. I therefore, concluded, that it was too strong a grower for frame work; but not being quite satisfied on that, and other points, I decided to try it on an open border, where it did better, but the produce was not comparable either as regards quantity or quality, with that of Paris Red Flageolet, planted at the same time side by side, and which really is a first-class Bean, but different altogether from Canadian Wonder, both in habit and size of pod. Nevertheless, in this week's number of THE GARDEN (see p. 462), your correspondent, T. Baines, has described the two sorts as one and the same Bean; he cannot however, I think, have grown both varieties, as with me they are wholly different kinds. I have grown Paris Red Flageolet now for some years and hope never to be without it, as it certainly is the best main crop kind with which I am acquainted, especially where plenty of produce is wanted. I gathered the last dish of it on the 11th inst., after 6° of frost, but it was protected with double hexagon netting. The plants which yielded this gathering were sown on the 25th of July, on a south border. The best Bean for an early crop I have found to be Sir J. Paxton, a kind which forces well, and with which I have several times taken the first prize at our June exhibition; but this year, owing to trying Canadian Wonder instead, I had none to show. I shall certainly not try the latter again.—W. DIVERS, *Wierton House, Moidstone*. [Your correspondent, who has sent samples of two varieties of French Beans, under the names of Paris Red Flageolet and Canadian Wonder (which are identical), has not got the Flageolet Bean at all, those sent being as different from that variety as the dwarf Negro is from Dan China. I enclose a sample of the Paris Red Flageolet, which I have cultivated for years, and which I grew side by side with the Canadian Wonder. The year during which the latter came out I, as well as numbers of others, proved it to be one and the same thing as Flageolet. As you will see, the true variety is as large again as your correspondent's Bean, different in colour, and quite unlike it in shape. The full-grown Beans, and also the pods of the true Flageolet, are nearly as large as Scarlet Runners.—T. BAINES.]

Major Clarke's Red Celery.—Until this season I have had great difficulty in obtaining really good Celery, although I have tried several varieties, and have grown them to a large size. This season I have one long row of Major Clarke's growing side by side with others, but none of them are so good as Clarke's. It is solid, crisp, and exquisite in flavour, an opinion which all who try it will confirm. It is the only red variety which I shall grow next season.—D. S. GILBERT, *Court Garden, Great Marlow*.

THE FRUIT GARDEN.

THE GRAPE VINE.

THE Grape Vine (*Vitis vinifera*) deservedly occupies the place of honour in the catalogue of fruits. It ranks in importance next to Wheat, and, like the latter, has been the companion of civilisation from time immemorial—following in its wake to every region of the earth adapted to its growth, and forming one of the most important branches of husbandry in those countries favourable to its development. Its native country has never been clearly ascertained, but it has evidently been widely distributed at a very early period. It is supposed to have come originally from Persia, migrating westward through Egypt to Greece, where it was cultivated by the highly civilised Greeks with intelligence and skill, we are told, from the days of Homer to the latest date of their prosperity. They appear even to have been experts in Grape growing, and fond of experiment, though not free from superstition in some of their practices. Among other feats which they are said to have performed was one which has lately been revived as a secret. This was to produce black and white Grapes on the same cluster, and which they accomplished

“by taking a slip of the white and of the purple Grape, and, having split them down the middle, carefully fitting the halves to their opposites so that the buds when divided should meet. They were then bound together with Papyrus-thread, and placed in the earth in a Sea Onion, the juice of which aided the combination of the severed parts.” They seem also to have been quite as particular as our modern Grape-growers in the selection of sites for their Vineyards, and in preparing the ground, which they trenched over, throwing the soil into lofty ridges and exposing it to the action of the air, and in this condition it was left for a whole year before planting. Then as now, too, opinions were divided concerning the best season for planting, some preferring to plant in spring, and others in autumn. From Greece, the Grape found its way into Italy, Spain, and France, its distribution being aided by the Romans in their

conquests westward, and its culture, as a branch of husbandry, rose in the course of time to be of national importance in these countries. It is supposed to have been introduced into Britain by the Romans about the second century, while others imagine it to have been imported much earlier, but not to have been cultivated until the civilising Romans set the example. About the third century, Vineyards were planted in the most favourable parts of the country, and, as civilisation progressed, these became more common, and were cultivated more or less successfully for the production of wine and other purposes up till, or near the time of, the Reformation. The Vine does not appear, however, to have flourished so successfully in our island as to encourage its extensive cultivation, and, as the superior wines of the Continent came to be imported in greater abundance, its outdoor culture gradually declined, until it became a thing of the past. But, as the Grape declined in value for wine-making purposes, it rose in estimation as a dessert fruit, and was more universally grown. At first, according to early writers on horticulture, Grapes for the table were grown upon standards

in warm situations, and against walls. Gradually, as the demand increased with increasing wealth and a more luxuriant mode of living, Grape walls came to be heated with flues, in

order to ripen the fruit earlier, and so extend the season of supply. More than 150 years ago, it was stated by Lawrence, in his “Fruit Gardener,” that the Duke of Rutland, at Belvoir Castle, did “so much justice to the Vine as to have fires constantly burning behind his sloped walls from Lady-day to Michaelmas,” whereby he had ripe Grapes in July. Eventually, flued walls were covered with glass, and, towards the end of the eighteenth century, Vineries constructed in a complete and proper manner (for the period) were becoming common in the gardens of the aristocracy; but it was reserved for the

nineteenth century, especially since the abolition of duty upon glass, to witness the great and rapid extension of horticulture in every department, and notably in the culture of the Vine; so that now the Vinery is the common adjunct of every mansion and villa of any pretensions, and not unfrequently

Fig. 1. Section of a Span-roofed Late Vinery.

Fig. 2. Section of a Lean-to Early Vinery.

of the poor man's cottage; and the Grapes produced under our sunless skies are, thanks to the energy of English gardeners, hardly excelled in any part of the world. Having thus sketched briefly the history of the Grape down to our own time, I now proceed to cultural matters.

Site and Plan of Vinery.

The site should present facilities for effectual drainage of the soil and sub-soil, if required, and it should have a free and open exposure to the south, east, and west—more especially if span-roofed structures are to be erected—while at the same time shelter from prevailing winds must not be forgotten. But sheltering objects, such as trees or high buildings, should be distant enough to prevent any bad effects from their shade. Nothing is more injurious to Vines than shade, not to speak of the additional cost in the way of fuel that would be incurred by having to keep fires burning longer morning and afternoon. As far as practicable, a Vinery should receive the sun's rays from sunrise to sunset. The form of the Vinery must depend upon circumstances. If it is for the production of ripe Grapes any time between the New Year and Midsummer, then a "lean-to" is the best for that purpose. Experience has long proved that such a structure is better adapted than any other to receive and economise the heat and light of the sun during the winter and spring months. For late Grapes—that is, Grapes that have to be ripened between midsummer and the end of September or October—a span-roofed house (fig. 1) is the best. It should stand with its ends facing north and south, in which position it receives the light most equally. Fig. 2 is a section of an early Vinery of the right size and proportions. We have another form of late Vinery here which was erected about fifteen years ago, after the plan of the glass screens at Trentham, but made wider. It is a kind of structure adapted to the wants of the amateur, and those who have to grow plants in the same house. In such a case it is proposed to train the Vines on the top only, under the ridges, where the fruit would at all times be out of danger, while the sides would admit sufficient light for the other inmates of the house upon the floor. The house here is entirely devoted to Vines, which are trained up the sides as well, and the crops have always been excellent. As showing the advantages of a good exposure to the light, I may here mention that in this house the fruit always ripens a fortnight earlier under the ridges than that at the sides. The leaves also are of greater substance, and the wood better ripened. This is owing to the greater amount of sunlight which the Vines receive. The ridges stand above the top of the wall against which the house is built, and receive the sun's rays several hours longer than the sides every day. Camellias, Oranges, and such like, would do well in a house of this kind, and against the front lights Strawberries in pots succeed admirably in spring.

Construction and Heating.

The best plan, in most cases, is to employ a professional horticultural builder and engineer to carry out the plans according to order. I need only observe here that wide and lofty houses produce the best results, because they allow of a greater extension of wood and foliage, and can be maintained at a more even temperature, owing to the greater bulk of air which they contain. In a "lean-to," the back wall should be plastered and whitewashed. Lightness and elegance should be aimed at in the construction of the roof, and no more wood or iron should be employed than is consistent with strength and durability. The wires for training the Vines, too, should be stretched along the house 9 inches apart, and 18 or 20 inches from the glass. When nearer than this, vigorous-growing Vines send their shoots up against the glass before it is safe to tie them down, and get chilled by the contact. Heating power, in these days of wide panes and open laps, should be provided on a liberal scale. In fig. 2, which represents a Vinery 16 feet wide by 16 feet in height, I have shown seven rows of 4-inch piping—the least quantity that should be employed for an early Vinery of these dimensions. In localities subject to severe and lasting frosts during the forcing season, I should be inclined to add another single row, so as to be able, when needful, to keep the temperature of the house 50° or 60° above the outdoor temperature, without making the pipes

too hot, and thereby scorching up everything in their immediate neighbourhood to a dangerous extent. The pipes should also be arranged so as to distribute their heat equally throughout the house, and keep the air in motion. In the majority of cases, they are carried round the front or sides of the house, in a block; consequently, when they are heated, the Vines are scorched at the lower part of the house, while they are suffering from cold at the top. I am aware that those who advocate this arrangement suppose quite the contrary to be the case, but a little reflection will show such a supposition to be erroneous. In a lean-to Vinery, for example, where the pipes are placed close to the front wall, a current of heated air ascends in a direct line from the pipes, and, coming in contact with the cold glass roof before it has travelled more than a few feet, it at once loses a great part of its heat by conduction, and, before it reaches the apex of the roof, its temperature is still more sensibly diminished, and, escaping by crevices or the ventilators, is lost. This is what takes place in a Vinery at night, or at any time when the temperature depends solely upon fire heat, and it explains why the Grapes under such circumstances invariably ripen above the pipes first, and finish off, sometimes, a month later at the top of the rafters. Anyone may satisfy himself on this point by placing a thermometer at the top and bottom of the house when the pipes are heated, and noting the difference. All this, however, is overcome by arranging the pipes as shown in figs. 1 and 2. I have had all the pipes in the Vineries here re-arranged on this plan, with the best results. It is difficult to lay down a rule for ascertaining the exact quantity of pipes required in every case, so much depends upon circumstances and the materials used in construction; but I find, for early Vineries, that 1 foot of 4-inch piping to every 18 or 20 cubic feet of air is generally sufficient for the temperatures which will be hereafter recommended for the Vine. Considerably less piping is required for late Vineries. To keep the atmosphere of the Vinery in a proper state of humidity, I find no plan better than liberally sprinkling the paths and inside borders with water. The Vine is not a plant that delights in a steaming atmosphere. Still, when hard firing is necessary, a more steady means of supplying moisture is desirable, and for this purpose I can suggest nothing better than the usual evaporating troughs, which may either be cast on the pipes, or made of galvanised iron and fitted on. These troughs are less troublesome than flowing gutters communicating with the boilers, as the latter are generally either running over upon the roots of the Vines, or requiring to be filled up as the water in the pipes rises or falls, according to its temperature.

Ventilation.

It is necessary, especially in the case of early Vineries, which are generally going to rest about midsummer and requiring to be kept as cool as possible, that the ventilation should be ample. The usual and most simple plan is to provide openings at the highest and lowest points of the roof. These openings, which should in the aggregate be equal to about a quarter of the area of the roof, including the front sashes, are fitted with swing sashes, which open with a rod and lever, as shown in figs. 1 and 2, so that the ventilation can be regulated as desired. This plan is found safe and effectual enough in ordinarily careful hands, and airing is at all times chiefly a question of attention and judgment; but it has the disadvantage in early forcing, that no sooner are the front lights opened than a current of cold air rushes into the house and comes in contact with the tender foliage before it is more than partially warmed, thereby injuring the Vines in the long run, producing rust and other evils. The obvious remedy for this would, of course, be to heat the air before it entered the house, and some ingenious and successful contrivances have been adopted to effect this object; but they add so greatly to the already much-increased cost of heating, &c., as to be practically out of the reach of all but those to whom expense is no object. The annexed sketch, fig. 3, shows a simple plan of accomplishing the end in view, which I have tried when necessary with perfect success, and it is so inexpensive as to come within the reach of every amateur, however humble. A is the front row of hot-water pipes inside the front wall of the Vinery; B a row of earthenware pipes, joined with cement,

laid directly under them, and having a row of holes each $\frac{1}{2}$ inch in diameter and 3 inches apart on their upper side; C is the feed pipe, which projects through the front wall into the open air, and at which the cold air enters, and, traversing the earthenware pipes right and left, comes out at the holes at the top, and, passing round both sides of the hot-water pipe, in its ascent gets thoroughly warmed before reaching the Vines. A still more simple plan is to project a single pipe through the front wall to the front row of hot-water pipes, taking care that the mouth of the pipe is just under the hot-water one. This will admit a stream of warm air, and, if the pipes are placed about 4 feet apart, the ventilation will be ample. The outer ends of the pipes must be fitted with plugs for shutting off the air at

Fig. 3. Ventilating Pipes.

pleasure; and, if a piece of wire netting or perforated zinc is fitted into the mouth of each pipe, it will stop rats or mice from getting in.

(To be continued.)

PEAR NOMENCLATURE.

SOLDAT D'ESPEREN, Soldat Laboureur, Orpheline d'Enghien, Beurré d'Aremberg, Glou Morceau, Beurré d'Hardenpont, and Colmar d'Hiver! Here we have seven names, but who will undertake to say exactly to what sort they each respectively belong? Pears are proverbially capricious as regards both the season of their ripening and the quality of their flavour; but it seems that caprice attends even the choice of the names under which they are presented to the public. And this is not owing to the number of their synonyms, but to the fact that a Pear tree is often sold under a name that belongs to another sort. Taking M. Jamin's list of "Pears worth growing" given in *THE GARDEN* for November 15th, I would enquire whether the Pear which he has called Soldat Laboureur is not the same that is usually sent out under the name of Soldat d'Esperen? From the period he gives of its ripening I should think that it must be. Soldat Laboureur I have always identified with Orpheline d'Enghien, and I was surprised to find M. Jamin making Orpheline d'Enghien and Beurré d'Aremberg synonymous, having myself always regarded them as two distinct sorts, though greatly resembling each other. Our Soldat d'Esperen, like M. Jamin's Soldat Laboureur, ripened here three weeks ago, whereas the Orpheline and the Aremberg are still hard, and are seldom fit to eat till after Christmas. That there are two Pears bearing respectively these names, Orpheline d'Enghien and Beurré d'Aremberg, the fruit catalogues of Mr. Rivers (no mean authority on Pears) will show. I was aware that in the published transactions of the Horticultural Society mention was made of the introduction of the Beurré d'Aremberg; and, on referring to the fifth volume, I found a description of it at page 406. There is another account at page 198 of the seventh volume, and a reference to the fact that there was at that time another Pear, the Glou Morceau, which had been sent to England as the Beurré d'Aremberg. On the opposite page there are beautifully-executed portraits of each, and no one, on looking at them, could for a moment mistake the one for the other. But I looked in vain among the synonyms of the Beurré d'Aremberg for Orpheline d'Enghien, the only other names being Duc d'Aremberg, Poir d'Aremberg, and Beurré Deshamps. The confounding of this Pear with the Glou Morceau ceased, we may suppose, when the Horticultural Society settled the matter in 1826; but M. Jamin has given us another point to investigate; his list includes the last two of the seven names given above, namely, the Beurré d'Hardenpont, and the Colmar d'Hiver, to each of which he gives as synonyms the Glou Morceau. These two names occur in the list of the forty-six "Pears worth growing;" and those who possess the Glou Morceau of the Horticultural Society, and know it by no other name, would probably like to be informed by M. Jamin whether it is identical with either of those, and, if so, with which? For we can hardly suppose that a Glou Morceau, when trained to a

south or west wall should be called a Colmar d'Hiver, or that it becomes a Beurré d'Hardenpont when grown upon an east or south wall, the situations recommended by M. Jamin. At present my seven names appear to be represented by four Pears only; but I should be glad to be better informed on the subject, and to be quite sure of what the addition to my stock of Pear trees would really be if I sent for either the Colmar d'Hiver or the Beurré d'Hardenpont. Synonyms, when they are known to belong to one fruit only, do not occasion disappointment. Whether we order it under the name of Dumelow's Seedling, or under that of Wellington or Normanton Wonder (it is known by the latter name in this locality), we know that we shall get the Apple we require; but confusion appears to have attended the names of Pears, especially of those which came to us in the early part of the present century. What is the Beurré Spence for example, is it identical with the Urbaniste as some say, or is it, as M. Jamin tells us, a name that was formerly given to the Flemish Beauty; or, again, is there a third Pear of that name? In the naming of fruits, some confusion may have been occasioned by the different names given them by foreigners and by ourselves; the Jargonelle of the French, for example, is an inferior Pear to our Jargonelle, for which they have a different name, and to the Chasselas de Fontainebleau Grape we have given, as every one knows, the name of the Royal Muscadine. To such changes of name may, perhaps, be traced the uncertainty which belongs to the names of some even of our favourite Pears, and M. Jamin would be rendering us a service if he would give the subject the attention and research which it evidently requires. I may add, in reference to Apples, that, until lately, Mr. Rivers's catalogue contained one called the Waltham Abbey Seedling or Golden Noble. The history of this fruit may throw some light on the way in which two separate kinds come to bear the same name. At p. 268, Vol. V., of the *Horticultural Society's Transactions*, we read that this Apple was raised at Waltham Abbey about the year 1812, from a seed of the Golden Noble, "to which it bears a strong resemblance, but is much larger." There must, therefore, now be, supposing the parent tree to be only one of many still existing, two Apples called the Golden Noble, though only one known as the Waltham Abbey Seedling. Of the latter I would remark that it is so fine an Apple, so certain and so abundant a bearer, that I think Mr. Rivers would have done well to have retained it in his catalogue.

B. S.

THE CHESTNUT HARVEST IN THE APENNINES.

THERE is festival now in the cottages of North Italy. As you walk at evening among her mountains and pass through her homely villages, a red light of wood fires comes streaming upon you from open cabin doors and from between the chinks of clumsy window shutters, and noisy sounds of revelry fall around. For this is the season when the Chestnuts are ripe, and the peasants are making merry by dark for the work they have had during the hours of day, and they are glad for that harvest which is to them the most bounteous of the year. High up, among the Chestnut woods, the sad leaves lie damp upon the ground, where the mossy turf is so moist that the Mushrooms are spoiled ere they be grown. The country looks tenderly forlorn that was so gay with its vintage in September. The trees shed their foliage early in Chestnut-wooded districts, and already the tints have little left that is freshly green, since the leaves are yellow upon the boughs, and are scattered, day by day, more thickly to earth. There is no hot sunshine, no blue light that is misty with heat; yet the valleys can still smile in their soberer mood, when chance and glorious sunbeams strike across the land, or when the rain ceases and bright days come back, here and there, with warmer breezes. The swollen rivers abate when the deluge ceases, if only for a day; and as you walk upon their banks the waters are limped again, yet green from their depth with an intenser colour. And wandering beneath the Chestnuts, no sense of damp or dreariness oppresses you now that sunshine is abroad once more, for the yellow-tinted leaves wave brightly overhead, and the yellower ones that are scattered rustle pleasantly beneath your feet, while now and again a quick sound breaks the stillness, and that is the fall of the fruit. Since the middle of October you might have heard it when you were in the woods, for the Chestnuts began to ripen at that time, and the brown-burnished fruit to peep from out its prickly shell. But scarcely before the end of the month in the Apennines does the Chestnut harvest begin in earnest. There is an interesting account of this in the *Evamier*. There are divers kinds of Chestnuts, and the gathering of each dates properly from a different day: the so-called "timely Chestnuts," that ripen before the commoner sorts—but these trees are rarer and the fruit is finer than of others; the late Chestnuts, that of their own accord do not fall sometimes till November—but these trees are often thrashed during the general

harvest for the greater convenience of the gatherers. Companies of women and girls greet you now upon your walks. They have little bags of sackcloth slung around their waists, and rough wooden tweezers in their hands, with which they open the spiked husks where the fruit lies yet in its green case. They are merry; they laugh and talk, their shrill Italian voices sounding shriller to English ears in the harsh Genoese dialect. Here a man has come to the aid of the girls, and has climbed to the top of a huge tree that he may the better thrash down the fruit. It falls in prickly showers upon the crackling dead leaves below; but the women seem little to fear any hurt from thorns, for they tread boldly amid the heap, often with bare feet, and take the harsh shells within their hands to open them. All day the people are at work. They are almost all women at this task, for the men are labouring in the fields. Some few of them return home at midday to cook and to carry the dinner for brothers and husbands without; but most of them remain in the woods till dusk, and eat their cold "polenta" at midday, resting upon the banks. Towards dark, the great baskets are piled up that have been filled all day from each woman's sack, and then the girls lift them upon their heads or shoulders, and pick their way deftly along the stony paths with the burthens. Sometimes the loads are too heavy and must be left for the men; but this does not often happen, for these peasant women are strong, with a beautiful ease of strength, and proud of their power. So, whether the day has been dark and cheerless, or whether the kind autumn sunshine has been there to brighten up all anew into a beauty more beautiful than summer-time, the women have been at work in the woods, and now the recreation hour has come. Within the cottages the great fire is lit upon the hearth that is in the chamber's midst, and the pot is put on to boil, and the rough wooden benches are drawn around, and men and women meet after their labour for fun and jollity at the first of the Chestnuts. When the "minestra" has been eaten or the "polenta," then the pot is taken off, and the great chain is put aside from whence it hung, and the "padella" is brought forth, upon which the Chestnuts are to be roasted. The red wood-fire flickers and flames upon the hearth amid its heap of embers, throwing fitful dashes of light upon the faces around—calling into sudden gleams the copper vessels, and platters upon the dingy walls. Again the bold flames die away, and there is only a lurid mass of cinders, and then the women toss Chestnuts in the pan and the men slit the brown hide of other Chestnuts that are yet unroasted, and they all chatter and gesticulate the while, in a fashion so quick and eager, and with voices so high and thrilling, that foreign ears, to whom the shrill dialect is unknown, might fairly hear therein the words of an angry quarrel. The Chestnut harvest lasts some three weeks or more, and when the fruit is all gathered in it is spread above the open rafters that form the roof of every kitchen in these Italian cottages—there to be dried during winter by the fire's heat from below. And when the Chestnuts are dried, and the outer skin has been cracked off by the heat, then they are ground in a mill, so that the flour goes to make Chestnut bread and cakes and porridge during the barren season when there is little fresh food to be got by the poor. The dried Chestnuts are boiled whole likewise—so that, in one form or another, the common production of the woods provides nourishment during this time for all the peasants throughout the land. This is the Chestnut harvest in the mountains, for in the mountains it is most an institution and an event, seeing that here there cannot always be so lavish in-gatherings of other crops and fruits as fall to the lot of people living upon the sun-baked shores of the Mediterranean. Nevertheless, upon the Riviera as well there is a Chestnut harvest and merry-making thereto. All along the shores from Genoa to Nice and from Genoa eastward, towards La Spezia, the trees grow richly upon the sides and cones of hills that turn inward from the sea or upon promontories above the water, wherever the Palms or the Stone Pines have not monopolised the room. And the soil here is so fertile, with streamlets that water and freshen it, and sun that shines hotly for many months upon its face, that the Chestnuts ripen more quickly and grow larger than upon the hills of the Apennines, so that they can be sold in the towns, and even exported to foreign lands, thus proving a good source of gain to the peasants. The greater luxuriance of the crop does not, however, make the greater quaintness in the manner of celebrating the season; and, to see a Chestnut country in beauty, there is no place like the valleys of the Apennines. Upon the shores there are the great rains as well that come pouring down from the skies to saturate the fields, and hurricanes from the sea that tear the branches from the trees, and cast down the rough little stone walls which divide the lands of different owners; yet there are not so many cosy gatherings of friends and neighbours around kindled logs. The trees do not so early shed their leaves upon the coast as in damper and colder districts, but the deeply golden colouring is over the hill-sides, broken only by the dark relief of Pines and Fexes.

The Viceregal Gardener on the Lambton Castle Grapes.

—As considerable uncertainty seems still to exist regarding the large bunches of Grapes that were exhibited at the Belfast show on August 20 last, I think it due to Mr. Hunter to communicate the following circumstances. The bunches in question were presented by the Earl of Durham to His Grace the Duke of Abercorn, and brought here immediately after the show. His Grace being desirous to show them to the company at dinner, the bunches were suspended from arches. In suspending them, I had ample opportunity of examining the bunch that has been the subject of discussion, and had there been any attempt at amalgamation, I should certainly have seen it. From the eye from which the bunch started to the point where ramification commenced, there was about 4 inches of true stem, perfectly round, with no sign of flattening throughout the remainder of the bunch. The immense size of the bunch gave the berries a small appearance, but, on comparing them individually with others of moderate dimensions, there was little difference; and, though they were not well coloured, many of the berries had the hammered surface. The eating qualities of the Grapes were very good, the pulp being remarkably firm and sweet. There need be no doubt whatever entertained regarding the bunch in question being one genuine bunch.—G. SMITH, *Viceregal Gardens, Dublin, in Gardener's Chronicle*. [The above should certainly set the point at rest, though all aware of the many fine bunches grown in the same garden year after year by Mr. Hunter, require no evidence as to the rumours circulated about the "grafting" of the bunch, &c.]

A Selection of the finest Pears proved in England.

Doyenné d'Été	Comte de Lamy	Maréchal de la Cour
Jargonelle	Flemish Beauty	Beurré Superfin
Williams's Bon Chrétien	Désiré Cornelis	Doyenné du Comice
Louise Bonne of Jersey	Marie Louise	Glou Moreau
Jersey Gratioli	Baronne de Mello	Winter Nelis
Urbaniste	Thompson's	Beurré Rance
Fondante d'Automne	Beurré Bosc	Beurré Sterckmans
Beurré d'Amanlis	Duchesse d'Angoulême	Joséphine de Malines
Suffolk Thorn	Beurré Diel	Bergamotte Esperen
Sackel	Beurré Hardy	Easter Beurré

Of the above—

Marie Louise	Glou Moreau	Easter Beurré
Beurré Bosc	Beurré Rance	Beurré Sterckmans
Duchesse d'Angoulême	Joséphine de Malines	Désiré Cornelis, and
Beurré Diel	Bergamotte Esperen	Winter Nelis
Doyenné du Comice		

should be grown against walls.

Choice List for Standards.

Jersey Gratioli	Louise Bonne of Jersey	Doyenné d'Été
Doyenné du Comice	Suffolk Thorn	Comte de Lamy
Citron des Carmes	Thompson's	Knight's Monarch
Jargonelle	Beurré d'Amanlis	Althorpe Crassane
Williams's Bon Chrétien	Swan's Egg	Marie Louise, and
Aston Town	Croft Castle	Beurré Superfin
Beurré de Capiaumont		

It should not be forgotten that Pears trained in any of the closely-cut forms should always be grafted on the Quince stock.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Heavy Crop of Strawberries under Glass.—On visiting Mr. Westcott's market garden at Topsham, the other day, I found thousands of Strawberries in pots under glass in all stages of growth, some being in flower, while others were loaded with ripe fruit, and the crop in all cases was so heavy that liberal thinning had to be resorted to. A handful of shoots removed in my presence literally swarmed with small green fruit. It seems, indeed, that Mr. Westcott can obtain as fine Strawberries, and as many of them, during these short days as in the month of May.—J. B.

New Late Pear.—Among late Pears, few surpass Souvenir de Sannier. Its deep yellow rind, flushed with red, makes it a very ornamental fruit; while its flavour is remarkably fine. It ripens late in October. The Beurré Amande, of the same grower—M. Sannier, of Ronen—a fruit of bright canary-yellow colour, having a distinct flavour of Almonds, does not ripen till the middle of November.—H. N. H.

The White Muscat of Frontignan.—This, supposed to be of Spanish origin, is the fruit (says the *Revue Horticole*) from which the Frontignan and Lunel sweet wines are made, and extensive vineyards of it may be found in the departments of the Pyrenees; but in the central provinces of France it is only grown as one of the sweetest and most highly flavoured Grapes for table use.

To Prevent Fruit Trees from Splitting.—It frequently happens, in very fertile regions, that trees split hub from hub through sheer weight of fruit. We saw many instances of this wherever a small garden had been planted in the foothills of the Sierras in California. The common mode of prevention is to prop up weighty branches with a piece of shingle. Isaac Lewis, of Hopkinsville, Ky., gives, in the *Practical Farmer*, another plan:—"When I find a forked tree that is likely to split, I look for a small limb on each fork, and clean them of leaves and lateral branches for most of their length. I then carefully bring them together and wind them round each other, from one main branch to the other. In twelve months they will have united, and in two years the ends can be cut off. The brace will grow as fast as any other part of the tree, and is a perfect security from splitting. I have them now of all sizes, and I scarcely ever knew one fail to grow."

THE INDOOR GARDEN.

IPOMÆA HORSFALLIÆ AND PASSIFLORA PRINCEPS (RACEMOSA).

WHEREVER winter flowers are in demand, and there is room for stove climbers of moderate growth, these two free-flowering plants should be introduced. To do them justice, however, they should have a little space in which to plant them, bricked off from the main bed or pit, where they will get a little bottom heat. The

ing racemes of the scarlet Passion-flower, or the more erect masses of brilliant tubular flowers of the Ipomæa. Unfortunately, like a good many things that are bright and beautiful, the individual flowers do not last long in perfection; but this defect is scarcely noticed, as the flowers succeed each other in such rapid succession through a good portion of the winter. When a moderately warm greenhouse adjoins the stove, branches of the plants just named might be introduced through an aperture, and trained over its roof. Many stove climbers might have their blooming season prolonged in this way, and notably that sweet white-flowered favourite, the Stephanotis

A New Gold Fern (*Gymnogramma decomposita*).

space for soil need not be large; from 18 inches to 2 feet square will be sufficient; but the drainage should be perfect, and the soil should be about equal parts of turfy loam and peat, with a liberal sprinkling of sand and lumps of charcoal. The latter will keep the soil open after the fibre in it has become decayed, and when, from frequent waterings, it may have a tendency to get too close. As a rule, heavy masses of climbers overhanging other plants in winter are not desirable, but in a lean-to house there is always the back wall to drape; a few climbers, too, trained thereby under a span-roof will do no harm, and there are few things more beautiful in winter than the long droop.

floribunda, which, provided its roots are placed under favourable circumstances, will ramble on from house to house, trained near the glass, and acquire an almost perpetual flowering habit, according to the varying temperatures to which its branches are subjected.

E. HOBDAV.

A NEW GOLD FERN.

(*GYMNOGRAMMA DECOMPOSITA*.)

This is a distinct and beautiful species, well deserving of a place in even the choicest collections of stove Ferns. It is a native of the

Andes of South America, from whence it was sent to Kew by Mr. Gair, of Falkirk. Its fronds are tripinnate and finely cut; in the latter respect, indeed, it forms a charming companion to the delicate silvery *G. pulchella* or *G. Pearcei*. The undersides of the fronds are clear sulphur-yellow, a colour which contrasts well with the vivid green of the upper surface. Treated like other species of the genus it succeeds perfectly. All *Gymnogrammas* and many of their allies, the *Cheilanthes*, like a warm and somewhat dry atmosphere. Syringing, which is so beneficial to Ferns generally, must be dispensed with in the case of Gold and Silver Ferns, water overhead being fatal to their health and beauty. They succeed best in a compost, somewhat firm and peaty; and they must be very carefully watered, as any sudden extremes in the way of dryness or excess of moisture at the root will soon destroy them. In growing these beautiful plants avoid over-potting them, and let the pots used be thoroughly well drained. B.

Browallia elata for the Garden and Conservatory.—This is a good old annual, by no means difficult to cultivate; and, when well grown, very effective. Where cut flowers of a bright blue colour are in demand this plant is capable of furnishing them, and for conservatory decoration it is most useful, as, when well grown in pots, it continues blooming from two to three months at a time, and may be had in bloom all through the summer, autumn, and early winter, without much trouble. I have had it in bloom till the end of February; and, when mixed with such plants as *Chrysanthemums*, among which there are no blue colours, the appearance of the collection is thereby much enhanced. In mixed borders out-of-doors this *Browallia* may also be used with advantage, continuing, as it does, in bloom a long time. From some plants, that have been in bloom from July to the 8th of November, we have been cutting three and four times a week. Those who have not grown this plant should, therefore, give it a trial.—JOHN CROOK, *Tyenham House, Wareham, Dorset.*

Ipomœa Horsfalliæ.—I can find no means of propagating this handsome climber; both cuttings and layers have failed with us. If there is a way of increasing it known to you, kindly give us some account of it.—A. [Your correspondent is not the first who has found a difficulty in propagating *Ipomœa Horsfalliæ*. Many who try to strike it, use, at first, the points of the shoots, or soft wood, as they would do in the case of the generality of other plants; yet, close observers, even without previous acquaintance or knowledge of a plant, can tell from appearance what likelihood there is of propagating it from cuttings of hard or immature growth, as the case may be. Any plant so soft and deficient in fibre as the young shoots of this *Ipomœa* are for a considerable length, bears reliable evidence of the difficulty or impossibility of striking it from the soft immature points of the shoots. It does not root over freely from even the best selected cuttings, especially where there does not exist especial appliances for propagation; but if, early in the spring, cuttings are made from the thoroughly ripe wood, and inserted in small pots in good propagating sand, placed in a brisk bottom-heat, they will root. For a new beginner, I should recommend taking a ripe shoot from the plant, and cutting a portion of it into single joints, and the other portion into two-joint sections, one to form the roots, and the other to push growth. With some plants of the nature of this *Ipomœa*, an inexperienced propagator will succeed with one of these descriptions of cuttings and fail with the other; it is, therefore, better to have two strings to one's bow.—T. B.]

A "Ladies' Plate" for 1876.—The council of the Preston Floral Society has decided upon establishing a ladies' plate, to be awarded along with other prizes to the successful exhibitors of six out of twelve stove and greenhouse plants at the exhibition of 1876. The winner of the first prize will receive £25 or plate of that value, and the society's gold medal, value £12 12s.; the winner of the second, £15 and the society's silver medal; the winner of the third, £10 and the society's bronze medal; and the winner of the fourth, £5. The twelve plants are to be shown to the secretary before the end of this month to be marked for future identification, and each one is to be a young plant, and in a pot of not more than 6 inches diameter, inside measurement. The plants so marked must be cultivated by each competitor on his own establishment, and out of the twelve marked plants six are to be chosen by the competitor for exhibition. At the time of marking each competitor has to deposit two guineas, as a guarantee that he will exhibit his plants at the appointed time, and each competitor pays an additional two guineas as an entrance fee, to defray the necessary expenses of printing and advertising. Sixty plants have been already entered, and it is likely that others will follow before the end of the month. The object of the council is to encourage the cultivation of young plants by amateur gardeners.

THE FLOWER GARDEN.

THE GIANT LILY, AND NOTES ON SOME RARE HARDY PLANTS.

WHEN in Suffolk in the end of August last, I was much struck with the beauty of *Siphocampylus bicolor*, grown as a hardy creeper on the outside of the Rectory at Belton, near Yarmouth. It was then a mass of bloom and presented a very uncommon and striking appearance. The situation is sheltered and partially protected by a verandah, and the plant is covered with a mat in severe weather. It reached nearly to the roof. It is a pity that so pretty a plant should be so seldom grown. When visiting Mr. Thompson's interesting nursery at Ipswich, I was much struck with the gay appearance of a bed of *Leptosyne maritima*, and made up my mind, if possible, to have a bed of it next summer. Mr. Thompson also had in bloom a very pretty *Calystegia oculata*, which I had never seen before. It is white with a deep purple eye. Mr. T.'s little home garden at Ipswich teems with interesting varieties, among which one might linger with pleasure and profit for many an hour. During a visit to Lord Walsingham, I had the pleasure of seeing *Lilium giganteum* growing in all its native luxuriance at Merton; the plants form an avenue on either side of a narrow partially-shaded shrubbery walk, and are intermingled with *Rhododendrons*, *Azaleas*, and various other shrubs and tall herbaceous plants. They are not nursed and tended with any peculiar care, and seemed to flourish all the better for being left alone. Thin, tall, strong stems were crowned with plump seed-heads when I saw them in September. *Dianella cærulea*, which I never before knew to be a hardy plant, was growing in great luxuriance in Mr. Nelson's most interesting garden at Aldborough Rectory, near Norwich; and, in the adjoining village, Mr. Cook, the miller, grows *Lilium giganteum* almost as well as Lord Walsingham. I saw *Viburnum macrocephalum*, a shrub far too seldom seen, growing in sturdy strength, at Earsham Rectory, near Bungay; and, at Ipswich, Mr. Thompson had *Colquhonia coccinea* in a condition which promised bloom before the close of the autumn. The late lingering of the mild weather has enabled many plants to bloom well here, which in ordinary seasons do but little good. Till last Wednesday I had *Exogonium Purga*, *Brugmansia sanguinea*, *Eurybia ramalosa*, and *Diplacus splendens* in full beauty in my garden. The Jalap plant (*E. Purga*) has survived two winters, and I have hopes that with care I shall keep the other three. Amongst the Croci collected and given to me by my friend, Mr. Elwes, I have flowered two quite new to me, which I believe to be *C. Cartwrightianus* and *C. lævigatus*. The former is a large and handsome flower, and the latter, though small, exceedingly delicate and pretty. Do any of your readers grow, and have they a bit to spare of, *Erodium incarnatum*? I have lost it. It is a favourite and I much wish to recover it. I was much interested by the account given a short time since of *Solanum lycioides*. How and where is this plant to be obtained. H. HARTER CREWE.

The Rectory, Drayton-Beauchamp, Tring.

FERNS IN PARKS.

At present, when gardening has reached such perfection, and has engaged the attention of so many amateurs, the cultivation of Ferns has become very general, and new varieties for both greenhouse and garden are continually making their appearance. Although they can boast of no flowers, their lovely fronds delight the eye, whether we consider the broad-leaved, the feathered, or the striated kinds. Some of the small Ferns are distinguished by graceful elegance, others reach a great height, often rivalling in that respect even the majestic Palm itself. Tropical Ferns are, as a rule, beyond the reach of many amateurs; but the indigenous sorts are well worth cultivation, as, though less splendid, they are very beautiful and varied. What, for instance, can be more charming than the male Fern (*Polystichum filix-mas*) with its large shining leaves, or the common Polypody, which flourishes luxuriantly among forest trees, the Wall-rose *Splenwort*, and the Bristle Fern (*Asplenium Ruta-muraria* and *Trichomanes*), which grow on rocks exposed to the sun, or the Hart's-tongue (*Scelopendrium*), and Maiden-hair, which love the shady banks of streams. In thickets, among trees and shrubs, our tallest Ferns abound, such as the male Fern, common Bracken (*Pteris aquilina*), and the Royal Fern (*Osmunda regalis*); in such situations they richly carpet the ground with their long and exquisitely cut fronds. How pleasant, after a long tiring country walk on a hot day, to dive into a forest glade and rest for a while on a bed of Fern and Moss, with a canopy of foliage overhead, so thick that the rays of the sun can hardly penetrate it. I am acquainted with a park of 300 acres almost entirely given up to the growth of Ferns, of which the proprietor possesses numerous varieties, but he prizes particularly the Royal Fern, which grows there in great abun-

dauce; the beauty of its fructification, which almost resembles blossoms, has caused it to be sometimes named "the Flowering Fern." Ferns require little culture, it is sufficient to plant them in damp and shaded situations. They, sometimes, appear to make no progress the first year; but they are so tenacious of life, that after lying dormant for a long period, they grow luxuriantly the following spring. There are few gardens where there is not space for a little Fernery, which, with little trouble, may be made into a charming spot; it will, besides, furnish a supply of foliage for floral decorations. Nothing is more effective than the common Bracken as a background for flowers.

COLOURS OF FLOWERS.

As a gardener not deeply versed in matters scientific, I have often been struck with the marvellous beauty, as well as diversity, of colours to be found in flowers. To thoroughly understand the blending of colours, and how the fertilisation of flowers possessing certain hues is pretty sure to produce others of a specific colour, one must needs be an artist. To suppose that a brilliantly-coloured flower has a special attraction for insects is no new idea, but to put forward the notion that rich colours are necessary in order to attract insects for purposes of fertilisation seems to me to be a mistake. Take, for instance, Mignouette; though its flowers are devoid of colour, yet bees will hover over them in myriads. In this case not colour but fragrance seems to be the attraction, the latter giving intimation to the bees that the food of which they are in search exists there in abundance. The remarks which you have quoted in reference to this matter seem powerful obstacles to the progress of the idea that colour is necessary in order to attract insects for purposes of fertilisation, and the conclusion seems obvious that brilliant colours have little to do with the matter. Indeed, if we were to follow the theory out to its fullest extent, it is obvious that none but brilliantly-coloured flowers could exist, inasmuch as no others would be fertilised. Where, amongst wild flowers, is there to be found a variety of more brilliant and attractive hue than the scarlet field Poppy, and yet it is not so common as Charlock or Groundsels, or even Shepherd-Purse, none of which have flowers in any way very attractive? Perhaps, on further enquiry, it will be found that insects, after all, do not play such an important part in regard to the fertilisation of flowers as has been imagined, and that, in our haste to ascribe to them such virtues, the existence of self-fertilising powers in plants may have been, to some extent, overlooked. There is another point to which attention should be directed. The pollen taken from a flower will only be effective on the pistils of others of the same species; and as the insects in their rambles proceed upon no definite plan, but alight upon one species and then on another, mixing all kinds of pollen together, it seems difficult to imagine that under such conditions fertilising properties will be retained. Nature says that autumn tints in leaves and fruits are often as rich as those existing in flowers, so also are the hues of the foliage of many plants, both tender and hardy, at all times. Of what use, therefore, are such rich hues in foliage, the normal colour of which should be green? What one would like to understand better is this—Why is it that plants wholly of the same species, and, in all other respects, alike in growth, in foliage, in habit, in period of blooming, growing in the same soil, and existing under exactly the same conditions, should yet produce flowers of such wondrously diverse hues of colour? In garden varieties of plants, most of this diversity is due to hybridisation, but the efforts of the hybridist in this direction differ from those of insects, inasmuch as, whilst theirs have no aim beyond the maintenance of life, the efforts of the hybridist are directed by intelligence towards securing a specific object. Of course, with such efforts have been combined the ennobling influences of cultivation, and what these alone have done in the way of improving the size, quality, and colour of flowers, no pen can adequately describe. High cultivation also effects other changes in plants, into the character of which it is unnecessary now to enter.

A. D.

WALLFLOWERS IN LONDON MARKET GARDENS.

FROM Christmas to May these are brought to market in quantities, varying more or less according to the mildness or severity of the season; in February, however, they are most abundant, being then sometimes brought into Covent Garden in waggon loads. The spikes of bloom are cut about 8 inches in length, and are tied with a wythe, or piece of matting, into little bundles, such as could be grasped with the two hands. Every grower saves his own seeds, and sows them, in the succeeding February or March, broadcast in beds in the open air, transplanting, when the young plants are large enough, in rows

1 foot or 15 inches apart, under fruit trees, or between lines of fruit bushes. The practice of sowing thus early differs entirely from that of the private grower, who, as a rule, sows his seeds in May or June; he has then to wait till the succeeding April before he can get a full crop of bloom, and his plants continue to flower until July; whereas, had he sown his seeds in February, transplanted his plants into any odd corner or reserve ground, and in November moved them into his spring flower beds, he would have had flowers at Christmas instead of April. Moreover he must lift his plants in May, long before their mass of bloom is exhausted, in order to make room for summer bedding plants, and thus a loss is experienced. This is one of the crops that thrive well in a shady place, and, although somewhat drawn during the summer time, the plants are too hardy to be injured when cold weather comes; indeed, they rather enjoy the change, as then the trees become denuded of their leaves, and, as our winters are not often very severe, the Wallflowers branch out and grow. When they become exhausted they are thrown away, with the exception of some of the finest, that have been marked and kept for seeding purposes, and which are allowed to ripen their pods undisturbed. After the Wallflowers are removed, the ground is manured and dug, and by this time the spring seedlings will be fit for moving, and are sometimes transplanted into the ground just cleared; or, if desired, it can be cropped with Beet, Sprouting Broccoli, or Brussels Sprouts; and the young Wallflowers planted in the space occupied by these the previous year. Market gardeners never keep their Wallflowers more than one year, as old plants are not so free growing or continuously blooming as young ones, which, when pinched, produce a multitudinous supply of young flowering shoots. Great care is taken every year to select the darkest-coloured and earliest-flowering kinds from amongst the immense quantities which are grown, and this continued selection of the finest and earliest sorts has a material influence upon their time of flowering. One year I procured some much-applauded varieties from different sources, and in March I sowed them, together with some of my own old-fashioned market strain (I may say old-fashioned, for during my experience of twenty-seven years I never grew any but the one kind, which was old-fashioned when I started), all on the same piece of ground, but each kind in separate patches. I transplanted them all under the same conditions, with the following result, viz.:—My own seedlings came into bloom in the last week of December, and have flowered well since, and, with the exception of a bloom here and there amongst the others, it was more than mid-March ere they came into flower, my old strain producing the most and best-formed flowers and the darkest-coloured ones, with not more than half-a-dozen yellow-tinged flowers and not one striped one amongst them; whilst amongst the others one-third of the plants yielded yellow and crimson-striped or yellow blotched varieties, which, in the market, would not realise nearly the price of my own old-fashioned market-garden kind; consequently, I must discard the new comers and still retain my old and valuable strain.

W. F.

Schizostylis coccinea.—Surely this plant is not half so much known or appreciated as it deserves to be. It is pre-eminently a flower for autumn, or, perhaps I should say, for winter, when the latter is mild. It is now the 25th of November, and I have a large row of it in full flower, and should the weather continue favourable it will keep in full beauty for at least another fortnight. With the exception of the Chrysanthemum, few November flowers are so hardy or so decidedly showy as is the *Schizostylis*; its masses of crimson flowers have a striking effect at this dreary season. The plant has a kind of *Gladiolus* look about it, but its habit is better than that of the *Gladiolus*; it is not so tall, and it throws up a greater profusion of spikes. When freely planted, as it ought to be, it will make a garden look gay far on into winter. It is of the easiest possible culture, perhaps too easy, as, if left to itself it becomes weedy. After plants of it have made their growth they should be lifted in July, sorted, and the strongest should be planted immediately where it is desired they should flower; the remainder may be planted out as a reserve for the following reason; without this precaution it throws up a quantity of stems that seldom bloom satisfactorily.—THOMAS WILLIAMS, *Ormskirk*.

A Golden-leaved Plant (*Diplopappus chrysophylla*).—Referring to this plant (see p. 421), I would be glad to know how it can be struck "freely." Of the plant sent us by Mr. Niven about two years ago we have raised a couple of little plants, now 1½ inches high! We find it as slow to strike as *Diosmas*, *Heaths*, and such like hard-wooded plants. Is *Diplopappus chrysophylla* "perfectly hardy" in England and Scotland? At Mr. Gorrie's garden in this neighbourhood it has stood the last three winters at the south end of his house, as well as the silver variety, *D. argentea*. This last makes a beautiful companion to the *chrysophylla*, and both are admirable

as foliage for cut flowers, and last seemingly an unlimited time in water. We have a pair of glasses, the foliage in which consists of *Artemisia annua* and *D. chrysophylla* in the one, and the silver variety mixed with the *Artemisia* in the other; purple flowers among the gold plant, and crimson or pink with the silver. The flowers and *Artemisia* have been renewed some dozen of times, but both varieties of *Diplopappus* are as fresh as when cut some weeks ago off Mr. Gorrie's bushes. The glasses being on a level with the eye, the "rich yellow pigment" of the one, and the pure white stalks of the other, are very attractive, and the habit of both most suitable for centres of nosegays in water. At this season I am not aware of any plant out of doors that has such a delicate bright shade of green (like the *Larch* in early spring) as *Artemisia annua*; always pleasing, it is now peculiarly refreshing to the eye. It is still growing, and has stood the five or six degrees of frost we have had here with impunity. Like all the *Artemisias*, it has a strong aromatic smell, but it need not be touched by those who dislike southernwood.—F. J. HORE, *Wardie Lodge*.

The Origin of the White Japan Anemone.—*Anemone Honorine Jobert* is not a garden hybrid between *A. vitifolia* and *A. japonica*. The variety originated at Verdun-sur-Meuse about sixteen years ago, in the garden of Mr. Jobert. From there the plant came into our hands in 1860, through my grand-uncle, Mr. Gustav Memminger, of Verdun, a great amateur of plants, after whom the *Eschulus Memmingeri* is named. Mr. Jobert, his friend, obtained the *Anemone Honorine Jobert* from a large tuft of the old *A. japonica*, with red flowers, from which plant a root branch flowered with pure white flowers. Mr. Jobert successively cut down all the red flowering branches, and so raised the white variety. Our nursery was the first to introduce the plant to commerce, under the original name given by Mr. Jobert, *A. japonica Honorine Jobert*. I have often seen at Mr. Jobert's the original plant from which the white variety was fixed, and, therefore, I guarantee the exactness of my assertion.—O. FROEBEL, in the *Gardeners' Chronicle*.—[We have always doubted the supposed hybrid origin of this fine hardy plant. After the *Tritomas* and the *Pampas Grass*, it is, perhaps, the finest autumn-flowering hardy plant that has been introduced to our gardens for a generation.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Novel arrangements of Hardy Flowers.—A lady correspondent, interested in improving on the common mixed modes of grouping herbaceous plants, proposes forming the following beds, and asks advice upon them:—1. *Clematis Jackmanii*, with possibly a pale *Clematis* intermixed; edged with Japanese *Honeysuckle* or one of the *Vines*. [Good.] 2. Bed of various *Fritises* and *Lilies*, edged with Irish Ivy or *Hepaticas*. 3. Common white *Pinks*, edged with pink *Bethsharrow*. [The *Pinks* are too short-lived in flower.] 4. *Roses* and Moss *Roses*, edged with *Myosotis dissitiflora*. 5. *Gloire de Dijon*, and General *Jacquemont* *Roses*, edged with white *Jessamine*. [Excellent.] Could spring flowering bulbs be mixed with these without injury? so as to have flowers in the beds before the regular plants come out. [Yes; spring flowers could be grown well in such beds, and would add much to their charms.]

Another Wild Vanilla Plant (*Rudbeckia subtomentosa*).—The article in your last number (see p. 479) on the Wild Vanilla plant, *Liatris odoratissima*, reminds me of another North American Composite in which there can be no doubt that *Commeline* abounds, perhaps as largely as in the *Liatris*. It is *Rudbeckia subtomentosa*, a desirable border species, growing about 3 feet high with three-parted leaves, and flower-heads of a full yellow, and the disk of a reddish-brown. So long as the plant is duly supplied with moisture at the root it gives no evidence of the fragrant principle hidden within its tissues, but a spell of dry weather, or any neglect of its aqueous requirements, which results in withering and browning of the foliage, invariably develops the agreeable odour of the *Tonka Bean*. Dr. Gray observes in his manual that the receptacle of this plant is sweet scented, but the fragrance of the foliage also when dried is undoubted.—W. THOMPSON, *Liverich*.

Sedum lividum.—Among hardy plants adapted for edgings or for covering slopes bordering footpaths or carriage drives, none excels this *Sedum*, which, when grown on rock-work, is not to be compared with what it is when grown where it can get plenty of moisture. When exposed to heat and drought, it becomes almost red in colour; but when grown where there is an abundance of moisture, it spreads rapidly and assumes a rich deep green hue. It roots on the surface with great rapidity, and may, therefore, be speedily propagated. Last spring I planted, for a sloping edging, very small pieces in a single line. It is now a perfect mass of green, scarcely exceeding an inch in height, 9 inches in width, and as level as a piece of turf. Its rich verdure is pleasant to the eye, and it always looks neat and needs but little attention to keep it in order. In spots where turf will not thrive, especially if rather damp, this *Sedum* will probably do well.—A. D.

Turfing v. Sowing Grass Seeds in Town Squares.—With reference to sowing Grass seeds on some new ground just added to Charlotte Square, Edinburgh, Mr. McNab makes the following remarks:—The sowing-down system in public squares is often attended with a good deal of trouble and anxiety, depending much on the weather at the time when the seed is put in. If dry and windy, it is often blown off the ground, and the walks suffer in consequence; and a second sowing has to be resorted to. I wish, therefore, to suggest the desirableness of turfing all the mired portions, so as to finish them off permanently at once. The expense will certainly be a good deal more than that attending the sowing-down method, but the turf looks infinitely better, besides being afterwards easier cut and kept.

Flowering Evergreens for a Lawn: *L. E. Arbutus Croomi*, *Berberis Darwini* and others, *Double Furze*, *Laurustinus*, *Portugal Laurel*, *Rhododendrons*, *Kalmias*, *Andromedas*, and *Yuccas* in variety.

THE LIBRARY.

THE AMAZON AND MADEIRA RIVERS.*

THIS forms a very handsome volume, of which Messrs. Chapman and Hall have just published an English edition. The object of the expedition was the exploration and survey of the banks of the Amazon and Madeira Rivers, and the adjacent regions, with the view of establishing railway communication where rapids and falls rendered the navigation of the rivers impracticable. Mr. Keller's notes, made on the spot, have been woven together by himself into a very attractive and interesting narrative, which, illustrated as it is by sixty-eight engravings on wood (some of them of remarkable excellence), forms a very instructive, and at the same time splendid volume. Mr. Keller's powers as an artist are remarkable; the striking tropical aspects of the region he describes being rendered with a spirit and effect that in some cases rise to the rank of first-rate art, while the engraver, by his sharp incisive style, has done full justice to the pencillings of the originals. Some of the vignette pictures, that serve the purpose of decoration to the initials at the commencement of the chapters, are very effective, especially one composed of the crown of a Palm with flowers and fruit, at the beginning of the Introduction, and that at Chapter II., composed of a vast trunk of a tree overgrown with Orchids, Bromeliads, and Ferns. Among the larger plates the "Halt under a Giant of the Primeval Forest" is very cleverly drawn and engraved. The "Lassoing an Alligator" is also a well-conceived and interesting illustration; and the "Head of a Tapir," swimming the river, pursued by dogs, is worthy of the pencil of Wolfe. "The First Interview with the Caripana Indians" should also be especially noted. It is a really excellent pictorial composition that might be enlarged to the dimensions of an oil painting, which would, if executed in a style fully equal to that of the present engraving, form a remarkable production. Two or three among the more eminent of French artists might be named who would so treat it as to produce a noble picture. The engravings are, indeed, superior in every respect to the illustrations generally found in books of travel. Perhaps the most remarkable of these striking and artist-like illustrations is the one entitled "A Giant of the Forest." It is called by the artist a "buttressed tree," and the natural supports have, in fact, somewhat the appearance of buttresses of masonry, as shown in the annexed engraving. The tree is the wild Fig, which attains to enormous dimensions in the Amazonian forests. Its wood is of a soft, spongy character, possessing singularly strong powers of vitality, by which it is enabled to adapt its growth to any situation, even under the most adverse circumstances. Any branch, or part of a branch, broken off and plunged into the ground will strike root and grow more freely than a Willow pole; "even," says Mr. Keller, "if a young tree be taken up by the roots, and the head planted in the ground where the roots recently were, the branches so planted will rapidly become roots, and the roots will develop themselves into branches, forming a new head of grotesque and singular character." The forest region skirting the course of the Amazon and Madeira Rivers appears to be a land of root wonders, of which those of the *Paxiuba Palm* are another curious example. This tree does not, like the giant Fig, throw out trunk-roots in the form of solid buttress-like masses, but obtains for itself trunk-support after another fashion, in the form of stilts, from which peculiarity it is popularly known as the *Stilt Palm*. From ten to fifteen of these root-stilts converge at about 8 or 10 feet from the ground, and from their meeting rises the trunk of the tree. But, in the mysterious twilight of these dense forests, it is the Orchids and Bromeliads that, above all, rivet the attention of the explorer; for, where a sunbeam, finding an opening through which to dart a ray of tropical light, happens to fall on a raceme of gorgeous Orchid flowers, or Bromeliæ, mingling with tree Ferns which, with them, clothe the trunks of the forest monsters to a great height, forming true "hanging gardens," the effect is dazzling and fairy-land-like, even to those conversant with the wonders of a tropical forest.

A BUTTRESSED GIANT IN AN AMAZONIAN FOREST.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

Flowers Obtainable for Bouquets.

FLOWER markets are now well stocked with material suitable for floral decorations of every description; amongst others, blossoms may now be obtained of Arums, Allamandas, Azaleas, Begonias, Bouvardias, Camellias, Chrysanthemums, Cyclamens, Eucharis, Epacris, Heaths, Fuchsias, Gardenias, Heliotropes, Primulas, Roses, Stephanotis, and Veronicas; Ferns, both British and exotic, may also be had. Therefore, with such abundance of material at command, most effective arrangements may be made. A hand bouquet exhibited the other day in one of the florist's shops in Covent Garden Market arrested my attention, being light and elegant looking; it consisted of the following flowers, viz., Gardenias, white Azaleas, white Bouvardias, yellow Rose buds (Maréchal Niel), bright blue Nemophila, and a few other light-coloured flowers, the whole being shrouded with fronds of *Adiantum cuneatum*, a fringe of the same Fern lying out over the paper round the edge. The Bouvardias and other light-coloured flowers were so mounted as to stand up above the others, an arrangement which tended to enhance the light effect of the whole. Button-hole bouquets were mostly composed of a Rose bud, Camellia, Gardenia, &c., backed by some Fern fronds and other light-looking flowers. Cheap bouquets were mostly made of blooms of Chrysanthemums and those of other out-of-doors or half-hardy plants. Attention should also be directed to the pretty crowns, crosses, and other devices made of Grasses and everlasting now exhibited for sale in Covent Garden for Christmas decoration, all of which, in their way, are most effective. The bursted seed-pods of the Gladwyn, loaded with coral berries, which were so much admired last season, have also already made their appearance; these, mixed with evergreens, form pretty decorations at this season.—A. HASSARD.

Flower Garden and Pleasure Grounds.

Little can be done in these at present. The weather, however, continues favourable for the prosecution of necessary alterations of all sorts, and the transplantation of trees and shrubs, wherever deemed necessary, should be attended to with as little delay as possible; and, in performing this work, if a little leaf soil can be placed around and among the roots, it will materially assist the production of new fibres; where the natural soil, too, is of a retentive character, a portion of sand or road-scrappings may be added to it with advantage. All shrubs or trees which are likely to require staking, in order to prevent wind-waving, should have that attention bestowed upon them when they are transplanted, and, unless the soil is very wet, a basin should be formed around each tree or shrub, and a good supply of water should be at once administered to it; this will tend to settle the soil around the roots and fibres, and will also help to steady the plants. As soon as the water has been fairly absorbed the basins should be filled in with soil, and when all has to be made level, a good mulching of partially rotted manure should be at once applied. Let every necessary attention be paid to the sweeping and rolling of walks, as well as of lawns, Grass belts, and verges. The Oak, and a few other sorts of trees, still retain a portion of their leaves, and their gradual falling renders daily sweeping up necessary. Late-sown annuals, which are intended to stand the winter and flower early in spring, will be much benefited by a slight protection of some sort, such as a few Yew or Laurel boughs stuck amongst them; and beds of Fuchsias, Tea-scented Roses, and other half-hardy plants (which have already been cut down by frost), should now be covered, to the depth of several inches, with tan, sawdust, or cinder ashes. Attend very carefully now to the wants of bedding-out stock of all sorts, more particularly to that portion of it which may still occupy cold pits and frames. Frequently remove all dead and decaying leaves, and cover up whenever danger from frost is apprehended. Little water will be required at present; but, where this is found to be really necessary, let it be supplied early on fine mild days, when air can be afterwards freely admitted in order to dry the foliage, if possible, before nightfall; and, in structures in which there are means of applying fire-heat, this should be done occasionally during fine days, accompanied by abundant ventilation to drive off as much as possible of the damp which, at this season, is so frequently injurious to such stock.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Indoor Plant Department.

Ferns should now be in a state of rest, which is better secured by a low temperature than by absolute dryness. A temperature of from 55° to 60° minimum is sufficient for stove varieties, while mere exclusion of frost will suit greenhouse ones. Such as are producing young fronds should be kept at the warmest end of the house, and

should, at no time, lack water. Tree-Ferns, too, should always have a good supply, for the surface-soil about them frequently presents a moist appearance when beneath it is injuriously dry. Cut away only such fronds as are quite dead. Hardy Ferns grown in pots should be placed in frames, on back stages in greenhouses, or plunged out of doors where water cannot lodge about them. Now is an excellent time to clean such plants of thrips and scale; when they have been thoroughly freed from these pests, the young growths come up vigorously, and have a much better chance of development than when old fronds, infested with insects, are present. Fumigating Ferneries, too, may now be beneficially practised, even oftener than in summer, inasmuch as the fronds in winter are harder and better ripened than in summer, and, consequently, less liable to injury. A good stock of young Ferns should be kept in a brisk moist temperature for supplying cut fronds, for furnishing purposes, and for filling ornamental baskets. Where spores have germinated, and have made a little progress, they should be pricked off in small patches at first, and afterwards, when a few fronds have been formed, the plants may be potted separately. Club Mosses also form good decorative subjects, the small kinds, like *Selaginella denticulata*, *Kraussiana*, and delicatissima being available for edgings, and the larger ones, like the varieties of *formosa*, *Africana*, *inequalifolia*, and others, make good substitutes for Ferns when kept growing, but when cut they soon fade. They may likewise be kept growing all through the winter, for as they grow so quickly, and can be propagated so readily, there is no necessity for resting them. Although they like plenty of water, even in winter, stagnant moisture is injurious to them.

Orchids.

A great variety of these is now in bloom, amongst which the following are, perhaps, the best, viz., *Oncidium Rogersii*, *ornithorhynchum*, *flexuosum*, *Papilio*, and *crispum*; *Odontoglossum Alexandrae*, *bictoniense*, *Uro-Skinneri*, *gloriosum*, *lavei*, *pulchellum*, *nubulosum*, *grande*, and *blandum*; *Zygopetalum Mackayi*, and *maxillare*; *Dendrobium moniliforme*, *chrysanthum*, and forced plants of *nobile*; *Cypripedium barbatum*, *Veitchii*, *Dominianum*, *concolor*, *insigne*, *longifolium*, *vexillarium*, *villosum*, and *Sedeni*; *Cymbidium Mastersii*; *Vanda coerulea*; some *Cattleyas*, *Laelias*, *Barkerias*, and *Angraecums*; *Calanthe vestita* and *Veitchii*; *Goodyera discolor*, *Masdevallia tovarensis*, *Mesospinidium vulcanicum*, and many others. Most of the plants in the East Indian department will now be approaching a state of rest, therefore a night temperature of 63° will be sufficient, with a rise of 10° by day. Lessen the supply of water to the roots in general, but at no time leave the roots or atmosphere without a moderate supply. Never permit Orchids to shrivel for want of water, particularly *Vandas*, which are apt to lose their foliage when kept too dry, thus impairing their health and appearance. Give plenty of water to *Calanthes*, and, if possible, never allow their blooms or those of any of the other Orchids to get wet, or they will spot and soon decay. Keep plants of *Cyclogyne cristata* at the end of the house where there is most atmospheric moisture, and give them plenty of water, but do not spill it about their rising flower-spikes. *Cypripediums*, *Laelias*, *Zygopetalums*, *Oncidiums*, and *Odontoglossums*, coming into flower, should be placed at the warmest end of the Mexican house, until their blooms open, when they ought to be removed to the cooler end, so as to prolong their period of flowering. A temperature of from 50° to 55° at night is sufficient for these. *Pleiones* that have done blooming, should now be re-potted at once, using a mixture of Moss, peat, loam, and sand, in well-drained pots. Give them plenty of water, and a position in the *Cattleya-house*. Sponge over the leaves of *Vandas*, *Angraecums*, and other Orchids, so as to keep them clean from insects, which can only be done by continuous attention.—B.

Indoor Fruit Department.

Grapes.—The preserving of Grapes in bottles of water is a system to which a good deal of attention has lately been directed. It relieves the Vines of their crop earlier than would otherwise be the case; but where it is unnecessary to start them before the end of March or beginning of April, ripe Grapes hanging on them do no harm. Where the Vinery can be kept free from damp, bottling need never be had recourse to; but where Grapes are hanging in a house in which bedding and other plants are stored, it is much better to cut and bottle the fruit than to let it hang. In cases in which a few bunches only are hanging in a large house, they should be cut, an operation by means of which much fire-heat is saved. Bottling consists in cutting the bunches, either with or without a piece of the shoot attached to them, and in putting the ends into a bottle full of pure water. These bottles may be of any size, and, when filled, should be placed in a fruit or other room in which there is a constant circulation of dry air, and a temperature of from 40° to 45°, in this way they

will keep fresh and good for months. Sometimes Grapes are preserved by inserting the stalks or stems of the bunches into Potatoes, Turnips, or Beets, a plan by which they may be kept in as good condition as in bottles of water. When preserved in a room, either in water or in roots, they are not, however, entirely exempt from damp and decay, they should, therefore, be looked over once or twice a week in order to remove all mouldy berries. Continue to prune and clean Vines, as they shed their leaves. In instances in which the wood is not yet thoroughly ripened, a little fire-heat and plenty of air should be given without delay, as much of next year's success depend on how the wood is ripened this season. Heavy rains being now prevalent in some districts, outside borders should be covered: young pot Vines which were placed outside when their wood was ripe should be removed under the cover of, say, a cold shed, in order that they may be protected from the weather.

Pines.—Material for renewing the bed in which to start early-fruiting Queen Pines should now be got in readiness; and tan, where it can be conveniently got, is the best for the purpose. Leaves are still used in many places, and very good fermenting material they make, Beech ones retaining heat best; but, where bottom-heat can be supplied by means of hot-water pipes, any kind will do. They should be collected now, and put up for consolidation, some six months before using them, in a heap in any out-of-the-way corner. The advantage which leaves have over tan consists in the valuable leaf-mould which the leaves furnish, while the spent tan is quite useless. No time should now be lost in collecting soil for potting Pines. The best is the top spit of an old pasture, where the soil, to the depth of 3 or 4 inches, is an impenetrable mass of fibre. It should be cut immediately after hard frost, as then most insects will have buried themselves considerably below the surface; few insects, however, affect Pine roots; potting-soil should, however, be free from earth-worms. That intended for next year's use is gathered by some now, and stored in Potato-pits like ridges, Grass-side downwards. Like it best just a month or two after it has been cut, and before any of its nourishing qualities have escaped.—J. Munn.

Peaches and Melons.—In the early house, Early York and Royal George Peaches, and Violette Hâtive Nectarines are swelling their blossom-buds without fire-heat, and with abundance of air; the mild weather of the autumn acting on the well-ripened wood, and the influence of a soaking of water on the inside borders, after a lengthened period of comparative dryness at the roots having had the desired effect of moving the trees, no fire-heat will be necessary for some time to come, unless very sharp weather should intervene. Peaches will bear a very low temperature if the blossoms be dry, and it is always advisable to force very slowly at first; time can be made up with a little pressure at the two swelling periods. Trees in cold houses, and even standard trees, will now be free of leaves, and the necessary pruning and tying or nailing may be performed; it is doubtful with trees under glass whether any time is gained by allowing them to be detached from the wall until spring, with the view of retarding the blossom; but it is a good plan to wash them with quick-lime mixed with a little soot, in the shape of a thin paint. Not infrequently, some variety of the scale insect will attack Peach trees under glass; as soon as detected, the affected parts should be gone over with methylated spirits, using a small hair brush. Fowler's insecticide, mixed with a little olive oil, may also be used with advantage. Now is the time to think about making contemplated alterations in the way of planting, either where new sorts may be wanted as a substitute for some unsatisfactory variety, or where a tree may have become exhausted; in every case choose young healthy trees when planting afresh; trees, which have been much cut with the knife when young, are sure to get cankered when they get older. The inside borders of Peach cases should have a good watering after the foliage has been all cleared away, and the trees tied, if done at once; but should the trees, for want of time, not be tied at once, it will be better not to defer the watering. Remove all the effête soil from the surface of the border, picking it out, where the roots are not very abundant, with a steel fork; top-dress with rotten manure, and again cover the manure with some fresh soil, and water it in; wash down the whole of the woodwork with warm water, and whitewash the back wall with quicklime.—W. D., *Canford*.

Hardy Fruit

As November is pre-eminently the month to plant, a good many may be anxious to know the best fruits to select for that purpose; I therefore venture to name a few, premising that what will suit one locality will not always give satisfaction in another. Among Apples the following are useful and pretty sure croppers, viz.—Dessert: Oslin, Early Harvest, Red Astrachan, Mother Apple, Cellini, Red Ingestre, Adams's Pearmain, Cox's Orange Pippin, Hubbard's Pearmain, Golden Pearmain, Scarlet Nonpareil, Old Green Nonpareil, Golden Pippin, King of Pippins, Downton Pippin, Pear-

son's Plate, Ashmead's Kernel, Melon Apple, Northern Spy, Ribston Pippin, Claygate Pearmain, Court Pendu Plat, Sturmer Pippin, Golden Harvey, Reinette du Canada, and others. Kitchen Apples: Keswick Codlin, Lord Suffield, Duchess of Oldenburgh, Alexander, Lord Burghley, Nonesuch, Gloria Mundi, New Hawthornden, Kentish Fill Basket, Small's Admirable, Tower of Glammis, French Crab, Warner's King, Blenheim Orange, Wellington or Dumelow's Seedling, Calville Blanche, Bedfordshire Foundling, London Pippin, Golden Noble, Red Beefing, Besspool, Winter Majeting, Northern Greening, with the new Apples Lady Henniker and D. T. Fish. These Apples are fit for use very much in the order in which their names stand, and will be found to furnish a good supply throughout the season. Pears—The distinction between dessert and kitchen Pears will possibly soon be altogether extinguished, as experience proves that the finest dessert Pears are also the best for stewing and all cooking purposes. However, probably such magnificent kitchen Pears as Uvedale's St. Germain, Catillac, Flemish Bon Chrétien, and such a hardy one as the Black Worcester will never go out of cultivation. The first-named is not only magnificent in size and appearance, but is also one of the best keepers, and most useful for stewing throughout March, and even far into April. Such a Pear, again, as the Vicar of Winkfield is equally adapted for stewing and eating, though it is not of first rate quality. Among the best varieties of Pears for orchard culture and pyramids are Marie Louise, Flemish Beauty, Beurré de Capiaumont, Louise Bonne of Jersey, Beurré Diel, Winter Nelis, No Plus Meuris, Napoleon, Ilaccon's Incomparable, Beurré d'Amanlis, Beurré Superfin, Suffolk Thorn, Glon Morceau, Easter Beurré, and Passe Colmar. For walls and more sheltered situations, Jargonelle, Autumn Bergamotte, Gansel's Bergamotte, Beurré de Amanlis, Summer Beurré, Beurré Giffard, Williams's Bon Chrétien, Duchess de Angoulême, Beurré Leon de Clerc, Huyshe's Victoria, Délices d'Hardenpont, Chantmontel, Prince Consort, Comte de Lamy, Beurré d'Arenberg, Knight's Monarch, Josephine de Malines, Ne plus Meuris, Jean de Witte, Bergamotte de Esperen, Beurré Rance, and Easter Beurré, of which no one can have an excess, as it is the very best late Pear in cultivation alike for dessert and kitchen use, though it will do well in many gardens as a standard or pyramid; it is also worthy of a wall anywhere, and the fruits are mostly much finer when so grown. Plums, perhaps, rank next to Pears in importance for table and kitchen use. Like Pears, also, some of the best Plums for dessert, such as the Golden Drop and the Jefferson, are also among the best for kitchen use. On the other hand those fond of a sharp Plum enjoy eating such fine kitchen sorts as the Washington, Diamond, Downton Imperatrice, Pond's Seedling, or Magnum Bonum. Still, the distinction between kitchen and dessert Plums is usefully preserved, and the following will be found among the most serviceable for culinary purposes:—Early Prolific, Early Orleans, Prince Englebert, Victoria, Goliath, Pond's Seedling, Magnum Bonum, Mitchelson's Diamond, Cox's Emperor, New Large Bullace, white and common Damson. Dessert Plums:—Early Favourite, Early Green Gage, Early Blue Gage, Early Mirabelle, Royal Hâtive, Angelina Bardet, Prince Englebert, Jefferson, Royal Hâtive, Huling's Superb, Reine Claude de Bayay, Reine Claude d'Octobre, Coe's Golden Drop, Coe's fine Late Red, Guthrie's Late Green, and latest and, perhaps, best of all, though rather a shy bearer, and often requiring to be forced into fertility by the knife on its roots—the Ickworth Impératrice, a Plum that shrivels on the trees almost to a sweetmeat, which, if gathered and preserved with care, may be sent to table right up to November. Many of these Plums will do well in open quarters as dwarf bushes, pillars, or pyramids. As to pillars, I have found that they seem to baffle the birds, whether from their novelty of form or not my experience is not long enough to say; but a line of these bore a good crop last year and the year before, when trees of other forms and on walls were almost totally denuded of buds by the birds. Plums also do well as cordons, within 15 or 18 inches of the ground; but almost all Plums deserve a north or east wall, on which most of them grow, and bear well, though many of them are quite as deserving of a south or west wall as either Apricots, Peaches, or Nectarines. For dessert they are equal to the best of them; and, as a preserve, the Apricot, fine as it is, can hardly rank with the Green Gage, Golden Drop, or Jefferson. Aspect makes a great difference in the appearance and flavour of Plums. Golden Drops are higher coloured here on a north-west than on a south wall. Indeed, on the latter they are more of a dull grey than a golden colour; but the quality of the sombre-looking fruit far exceeds that of the more showy, as is often the case with other things, besides fruit.—D. T. Fish.

Kitchen Garden.

"A good workman," it is said, "never complains of his tools," but few, I imagine, will deny that a good workman will do more and better work with a good tool than an inferior one; and in these days of dear labour, if we are to have the full advantage of his skill, it is

incumbent on us to provide him with the best implement that can be obtained. When I came here, six years ago, I found the men digging with a common soft clumsy spade, and, the soil being heavy, each man had an ingeniously-fashioned piece of wood for cleaning it, and nearly as much time was occupied in cleaning and scraping the spade as in digging. I therefore obtained some of Lyndon's patent bright steel spades from Birmingham; and, having overcome the usual amount of prejudice on the part of the men, I soon found both the quality and quantity of the work vastly improved. Parke's steel fork is another implement that ought to be in every garden; and, although the first cost of these improved implements will be rather more than that of ordinary ones, they will last so much longer as to be the cheapest in the end, without taking into consideration the improved work done with them, and the increased amount of it. Give abundance of air to Cauliflowers and Lettuces in frames; Endives for winter use may be preserved for a long time in the following manner where the space under glass is limited:—Tie them up when dry, lift them with balls, and pack them horizontally in dry ashes in a ridge against a wall, just leaving the ends of the leaves out. Straw or other coverings should be always at hand to cover them on the approach of bad weather. Jerusalem Artichokes keep best in the ground, but they should be covered with half-decayed dung or leaf mould to keep out frost. In some places it is the practice to leave them in the ground year after year. This is, however, a mistake, both as regards the early maturity of the crop and the size and quantity of the produce. The crop should be lifted in February just before growth has commenced; the largest tubers should be stored away for use, and the medium-sized ones planted on fresh land. I do not know how it may be with others, but our cooks are always ready for them, for soup-making and other purposes, as early in the summer as they are fit for use; and, to meet this want, annual plantations are necessary. Globe Artichokes, like almost everything else, have made wonderful autumn growth, and will therefore be more susceptible to injury from frost than usual; therefore, pack litter well round each plant, and, when frost sets in, cover over the tops also. Where there is a large demand for them early, a few strong roots may be taken up and potted in large pots, and placed in a cool house to be helped forward under glass in spring, but the roots must not be divided or disturbed beyond removing the weak offsets that are not likely to furnish heads.—E. HOBDAV.

WITCH-HAZELS.

(*CORYLOPSIS SPICATA*.)

THE *Corylopsis spicata* of Siebold and Zuccarini is very much grown in the gardens of Japan, where it is known by the name of Avomomi. In the "Flore du Japon" these naturalists also make mention of and describe another variety of *Corylopsis*, which they classify as *pauciflora*; this species, they say, is known by its smaller size, both in height and foliage, its slender branches, and particularly by its paucity of blossom. Thus, whilst the catkins of the *Corylopsis spicata* bear ten or twelve buds, those of the *pauciflora* only contain two or three. In spite, however, of these differences of growth, we are still of opinion that the latter is only another sort of *C. spicata*; for the *C. pauciflora* is also known by the name of Avomomi in those gardens where it is most cultivated—whilst the Japanese herbalists even classify both under the common name of *Rosa Midsuki*. A botanist of Japan, Keseak, has discovered among the lofty mountains of Kiusin, presumably growing wild, an unknown species of *Corylopsis*, to which Siebold and Zuccarini have given the name of *Keseaki*, in honour of its discoverer. The *Corylopsis spicata* is a spring-flowering shrub, blooming in February and March. It is very hardy, and can be grown in almost any soil. It may be raised from cuttings made of well-ripened shoots, taken during the summer and struck in heat.

THE ARBORETUM.

TRANSPLANTING PINES AND EVERGREEN SHRUBS.

By ROBERT HUTCHINSON.

At some time or other, in the course of every proprietor's tenancy of his estate, he finds it necessary to transplant. It may be that other improvements or alterations have rendered the sacrifice or removal of some favourite tree necessary; or it may be that the strips and belt-ings planted in former years for ornament or shelter require to be thinned, and the destruction of many healthy young saplings which it may be desirable to save, is, by this process, rendered inevitable; while, in other and not unfrequent instances, the bleak bare fields, unclothed with landscape beauty, suggest the wish to call into immediate existence the leafy grove and sheltering woodland, to adorn and add to the beauty, and consequent value, of the estate; and in each of these cases is the operation of transplanting resorted to with more or less certain success, according as it is carried out judiciously, at the proper season, and with due regard to the relations of soil and situation, and also to the proper choice of subjects operated upon. While thus the practice of transplanting both trees and shrubs may be said to be very general, if not universal, few instances occur in Scotland of its successful accomplishment in the case of trees of considerable magnitude; this arises, probably, as much from the greater difficulty and expense of adjusting the necessary operations to the increased natural requirements of the subject handled, as from any insurmount-

Corylopsis spicata.

able physical obstacle to the success of attempts to remove a large tree. It is rather a question of cost than practicability; for, if carefully done, the system may be applied with perfect safety to trees of considerable weight and stature,—the first principle requisite to be observed throughout the process being, that every part of the operation must be performed in the manner, and at the season, least tending to check the healthy circulation of vegetable life; otherwise, doubtless, failure will result, as has already in many instances throughout the country been the case; and money has thus been expended in vain, and the planter's hopes rendered merely nugatory. In prosecuting this system, then, the aim ought at all times to be, not to lift and re-plant the largest possible specimens, but to attain the utmost success with those plants operated upon. It must be admitted that at the best the practice of transplanting is somewhat opposed to Nature; and that even in perfectly successful cases, the plant sustains for a time a check, which is noticeable in the first season, in its new situation, by a much smaller development of foliage, with a total cessation in the formation of young wood; while, upon examination, the individual leaves seem dwarfed or stunted, and wither earlier than usual in autumn, thus indicating that the constitution of the tree has undergone a shock. During the second year in the new site, the same symptoms may be presented, sometimes in less, yet frequently in an aggravated degree; but gradually these pass away, and after the third or fourth year, although to that period less young wood than usual may have been thrown out, this torpid condition appears to have been the gathering up of fresh strength to repair the injury done to Nature, and she again resumes her functions with all the former, if not with increased, vitality and vigour. The art of transplanting resolves itself into two distinct systems. These are, first,—transplanting of saplings from 3 to 8 or 10 feet high, which we may here style horticultural transplanting; and, secondly,—transplanting of large trees or specimens for landscape or park-wood effect, which we may denominate arboricultural transplanting. Different methods of conducting the operation may be adopted, according as one or other of these two systems is selected. The general principles, however, are in both cases the same, and the same objects must be borne in mind

in either method, viz., to disturb the processes of Nature in the growth of the tree as little as possible; and, when disturbed, to provide a speedy and efficacious remedy. In choosing between the two systems, we undoubtedly prefer the first mentioned, as unquestionably safer, more economical, and progressive than the other; and where, from experience, we have been able to compare results, these are decidedly in favour of the smaller and more easily removed specimens; and if good trees be chosen, say from 4 to 8 feet high, for purposes of immediate effect, success will be attained with them, far more certainly, than by moving much larger trees; while the permanent results of selecting specimens of the sizes we have indicated are equally in favour of the younger trees. Large plants cannot be moved without the aid of cumbrous mechanical appliances, involving time, expense, and risk; and the end attained (if successful) by such a process is hardly commensurate, except in very limited and extreme cases, with the amount of outlay and labour required.

Transplanting large and heavy Trees.

The art of transplanting really large and heavy trees must ever be limited, for it is not applicable to the general purposes of utility. It can only be applied for ornament, and for wooding for purely picturesque effect. Doubtless, the system acquires a value of its own, when bare, bleak, unsightly grounds are clothed, and sheltered, and ornamented by its aid; but there is one essential to be carefully observed in adopting this extreme method of transplanting, and that is, to guard against merely moving large trees to mutilate them, or promote their decay. Into one or other of these evils the incautious planter is apt to fall, in attempting, without sufficient preparation, great care, and adequate machinery, to remove any large hard-wood tree or evergreen; and, where caprice or necessity renders it imperative that transplanting be carried out upon such a scale as this, it would be well that the expense of such operations be also taken into account beforehand, for to ensure success with heavy objects removed, the labour and time required must be neither stinted nor grudgingly given. The first point to be considered, under either of the systems of transplanting specified, is the selection of a proper subject. Assuming that the operation is to be performed for landscape effect, and that a large specimen, say 20 feet high, is to be moved; for unless it is desired to attain for special reasons immediate effect, we recommend (as before stated) for general purposes, the choice of much smaller plants, not exceeding 10 feet in height. The tree chosen must have a light well-branched head, with particularly clean and healthy bark on the trunk. Too spreading a top is to be avoided, for, as it is always preferable to secure a proper balance of power between the roots, on the one hand, and the head or branches on the other, and as the proportion of spread or roots in an ordinary average soil is about two-thirds of the diameter of the branches, so much less labour is required, and more certainty in obtaining a good root-ball secured, if a tree be chosen with a well-arched tapering or conical habit of branching, rather than one whose wide-spreading expanse offers more immediate shade. Tall, drawn up, narrow specimens, with few branches, should be avoided. They are invariably deficient in roots, and weakness in this essential particular is certain to predicate failure after removal. Certainly, in selecting trees to be transplanted, the head should always be the criterion of choice, for, independently of its indicating the future habit, appearance, gracefulness, and value of the tree, it is the best index to those unseen parts of its mechanism, the roots; and it may be stated as a rule, that the tree with the best head is sure to have the best root. The situation of the tree to be removed, is the next point requiring attention. An isolated position is the best of all for purposes of removal. The roots in such a case are generally better proportioned, and more equally disposed on all sides, and if the tree has otherwise a healthy appearance, these are more likely to be easily secured and safely moved in the operation of transplanting. The more confined the position of a tree has been in its early years, the fewer and weaker are its rootlets when it becomes tall, and consequently the less fitted are they to resist the interference and disturbance which transplanting causes; while, on the other hand, the more open and free to the influence and circulation of air the situation of the tree has always been, the more dense, numerous, and healthy are the underground fibres. Where, therefore, isolated specimens cannot be procured, we prefer selecting for our operations of removal, good trees grown in narrow strips, or upon the edge of a plantation. But, independently of the advantages of situation to the proper and healthy conformation of rootlets in the specimen to be removed, there are other considerations necessary to be borne in mind, which are of considerable moment in this particular, as bearing upon the general health and constitution of the tree. When planted in thicket, the plant is accustomed to a more regular and milder temperature than it would enjoy upon an open, exposed situation

Thus, in woods, precipitation would be less regular, the thawing snows and spring showers being absorbed by the loose bibulous mould, and, consequently, nourishing the spongioses in their retentive bed of absorbent earth, so that they in this way lay in a store of moisture to last during the drought of summer; and, owing to the peculiarity of the situation, the supply of food for the numerous rootlets, when required, is well provided for. Remove the tree to open ground, and the habit it has thus acquired is interfered with and changed. Place the specimen, by its removal, under the open vault of heaven, exposed to every breeze or gale that blows, and to all the vicissitudes of a changing temperature, and its constitution suffers from the change. The earth, it is well known, parts with its warmth by radiation to an open sky at one season, and at another imbibes an immoderate degree of heat from the direct unimpeded sun's rays. Hence, in such an open situation, to a tree or shrub hitherto unaccustomed to it, the climate proves excessive or extreme. Alternately the soil is saturated with moisture and seared by the inclemency of winter's frost, or parched and hard bound by the fervour of the summer's sky. Cold and frost-chilled blasts sweep unrestricted along the dew line, and melt away the sheltering snow, hardening and drying up the very fountains of its scarce sufficient moisture; and how, under these changes, and subject to these alternations of circumstances, can any tree, hitherto unused to such vicissitudes, and only recently placed under their influence, be expected to survive the extremes to which its new position have subjected it? Yet such is the history of most cases of transplantation. The specimens are chosen from overcrowded denizens of woods, and are quite unsuited for any such experiment. Can we wonder, then, if their planters meet only with disappointment?

Tree Planting in Exposed Situations.

In exposed situations, experience shows that timber trees planted for profit, should be placed at as early an age as is compatible with other circumstances, in the stations which they are finally destined to occupy. One method of attaining effect within a comparatively short period in such bleak tracts, is to cover the ground intended to be planted, with rapid growing nurses only; the Austrian Pine, *Pinus Laricio*, or *Pallasiana*, for example, will suit the purpose well, and when these have attained a height of from 4 to 5 feet, spaces of about 6 feet diameter should be opened at stated intervals, and into these openings healthy transplanted hard-wood trees be placed. These may be from 6 to 10 feet high, and be lifted with good root-balls, as will afterwards be described. Planted thus, the nurses do not, as too frequently happens, choke and overtop the smaller deciduous trees; and if the operations of transplanting are carefully carried out in this manner, the hard-wood timber will at once, when placed in its new situation, be found successfully coping with the Pines in growth, and the permanent results, so far as the value of the timber is concerned, will be perfectly satisfactory, while probably from six to ten years are gained in the period required for developing the wood for economic purposes. Another essential consideration to be borne in mind in transplanting, is the season of the year at which the operation is performed. As a rule, the functions of Nature will be less deranged if the tree be removed when in its annual dormant condition. The habits of the different species of trees, Conifers, and evergreen shrubs, are so various, that the same period of the year will hardly suit any two of them for transplantation. On the one hand, in removing plants in the autumn, they are at once in their new site, exposed to the injury which severe frost during winter may occasion; while, on the other hand, spring-planting subjects the specimens removed to what is frequently of more vital consequence to avoid, namely, the sudden setting in of chill winds in April and May, followed by drought. In the case of the Coniferæ and evergreen shrubs, this contingency should always be averted if possible; and we find, from personal experience, that these species generally succeed best, under any circumstances, if undisturbed in their old sites until the end of April at the earliest. Indeed, there are many of the varieties in these classes which, if judiciously and carefully lifted, may be so operated upon during the whole summer, or at any time, provided the spring winds or winter severe frosts are avoided. About the end of September, or early in October, is, according to our experience, one of the best seasons for transplanting these special varieties, provided the weather be favourable. For general guidance, let this consideration, namely, the alteration of temperature in the soil, as well as in the atmosphere, regulate, to a great extent, the season for transplanting, and decide between the two rival periods of the year for the process,—spring and autumn. In this climate, when severe frost prevails during winter (usually after Christmas), and then breaks up, we generally experience for some time a considerable amount of rain. During this season, and under such circumstances, it is impossible to prepare the soil, by digging or trenching (as should be invariably done), for trans-

planting operations. This is more especially true of the heavier soils. As soon, however, as dry weather supervenes, and the earth has drained off all superabundant moisture, advantage should be taken to dig and pulverise the soil to some depth, say 2 feet, preparatory to planting. Leaving the ground thus turned over, and broken perfectly fine during April and the early part of May, heat is absorbed by the freshly-stirred earth, and its temperature is thereby increased, which will go far to aid and promote the development of the young roots of trees which may, at this season, be transplanted when the weather sets in dry. The species most suited for removal at this period of the year are the various *Abies* genera, the *Pinus*, *Cedrus*, *Juniperus*, *Cupressus*, or, indeed, the *Coniferae* and evergreen shrubs generally. These may be removed of any size with impunity, if due regard be had to ordinary precautions, and to the general principles of phytology. But it is essential to the welfare of the transplanted specimen that the earth into which it is placed be dry. In fact, the surface-soil all round, having been exposed to the sun's rays, should be the first soil thrown into the pit, next the rootlets, for it is not only warmer, but drier, and more free, and, consequently, better adapted to the rapid repulsion of new spongioles. Care should be taken to give as little watering as is consistent with the foregoing remarks, especially in the case of shrubby evergreens. The surface of the ground may be once mulched after planting; but a better plan to adopt, if the specimens be small, is to puddle the roots well previous to transplanting, and after having lifted them carefully from their old situations. If watering should be requisite, owing to the setting in of very dry weather, it should be given overhead, *i.e.*, by syringing the foliage and branches of the newly-planted shrub or tree, which will tend to arrest the free perspiration of the leaves—a function which they invariably perform more profusely after transplantation, and which should, if possible, be checked till the roots have recovered sufficient hold of the ground to be able to supply the waste upon the system of the plant. This syringing may be applied several times daily, provided there be little or no sunshine, and will tend greatly to accomplish the object desired. In removing *Coniferae*, evergreen, and other shrubs, care must be taken to rack or sprain none of the rootlets by too hurriedly drawing the plant from the ground, and so curtailing the mass of little fibres at the extremities of the large roots; and in placing the plant in its new situation, the pit should be sufficiently large to admit of the rootlets being well and carefully spread out, receiving as wide a lateral arrangement as possible on all sides amongst the dry stirred earth. For, as no tree can form a healthy development of leaves and branches unless it be supplied with a corresponding healthy development of roots and feeders, should any injury be done to the smaller roots, no matter what the species of the tree, and no matter whether that injury be done intentionally, under the name of pruning, or accidentally in the operation of lifting, the progress of such a mutilated specimen above ground will, until the injury be repaired by a new growth of rootlets, be comparatively dormant or retrogressive. No doubt some have advocated root-pruning as an aid to success in the process of transplanting; but such practice we hold to be inimical to all the best modes of conducting the operation. Sufficient task is already imposed upon the constitution of the tree or shrub by the mere fact of its removal; and there is no need wantonly to increase its risk of failure by removing any of the small terminal rootlets, which, by Nature's fiat are indispensable to the welfare of all plants; and any injury from which these soft spongy organs are so liable to suffer during transplantation, either from undue exposure to the air and action of the atmosphere, or through their delicate outer coating coming into rough contact with any foreign body, such as the hands or the implements of the workmen employed, ought to be guarded against with the utmost care and nicety. We have known no case in which root-pruning, in tree or shrub transplanting, has been of the least advantage; but, on the contrary, consider that the most recently made rootlets should be preserved entire and undisturbed with the utmost care. This is another argument against the attempt to remove specimens from thickets or plantations, as before referred to; for in such situations the fibres are fewer and weaker, and also, owing to the close proximity to other trees, the underground roots are too much interlaced and mixed with others to admit of their being extracted without considerable injury, and losing many of their newly-formed spongioles.

Autumn Planting.

Another season of the year in which the operation of transplanting large trees is a good deal practised, is the autumn—probably from the end of September, during open weather, till early in spring, when buds have commenced to swell, and sap to flow or rise in the tree. While we prefer the later months of spring, say early in May, or about the end of April, for *Coniferae* and evergreen shrubs, and have frequently seen these varieties successfully removed at mid-summer, we prefer autumn for deciduous forest trees, especially

if they are large and heavy specimens; for about the end of September, or beginning of October, in the Scottish climate, at 2 feet underground (the depth at which some young rootlets bound), the mean temperature of the soil will average 52° to 65°, while the mean temperature of the atmosphere, at the same period, will vary in ordinary average seasons from about 48° to 55°. The soil being thus warmed, and closely approximating the temperature of the outer air, any unavoidable injuries which, in the process of transplanting, the roots of the trees removed may sustain from cutting, are the sooner and more easily healed over; while, at the same time, owing to the underground warmth and moisture, the growth and formation of fresh rootlets and spongioles are induced and promoted more than they would be in spring, when the temperature of the soil would be colder, having then fallen to about 38° to 40°; and when the want of these organs would be felt by the tree at a time when their loss could not be at once supplied, but which would by this period have been made good, in all probability, if the transplanting had taken place in autumn. As soon as the leaves of deciduous trees have performed their functions, and have fairly grown sere and withered, or been loosened and whirled from their branchlets by the frosty nights and gusty winds of October, the operation of transplanting forest trees may in favourable weather commence; and in removing these varieties of timber trees, it is well to do so in the order in which the various species come into leaf in spring. First, remove the *Poplars* and *Willows*, for in this latitude these begin to bud and leaf in the early part of April; then the *Larch* (small plants only), whose tassels are hung forth about the middle of April; next, the *Plane* and *Maple*; and then the graceful *Horse Chestnut*, and tall drooping-branched *Lime* and *Elm*, which usually leaf ere May has gone. Later in the autumnal months the proud giant trunks of the wide-spreading *Beech* and lordly *Oak* may be transported to other sites; while last of all, and with the early days of the young year, the *Ash* may be operated upon, for it will be well into June ere the delicate green of the pencilled foliage of that useful and ornamental tree completes the clothing of the forest for the year. Of all these, the *Oak*, *Ash*, and *Larch* will be found the most difficult to transplant successfully, the *Elm* and *Lime* most easy. Before leaving this branch of the subject, we may as well detail the comparative results of transplanting evergreens and shrubs during autumn and spring, so far as we are able to do so from personal experience. In the month of November, 1856, a thick shrubbery of evergreens (composed chiefly of *Portugal Laurels*, *Bays*, *Hollies*, *Irish* and *English Yews*, with a few *Conifers*), was formed at C——, at an altitude of 90 feet above sea-level, in a heavy rich loamy soil, with close retentive sub-soil. The plants were about 3 to 3½ feet in height. A moderately severe winter ensued, and the losses were about 50 per cent. of the plants used. This damage arose not so much from the severity of the frost, as from the chilling east winds of spring in March and April following, acting upon the specimens before they had established their roots sufficiently in the ground after removal. The blanks thus created were made up in the end of April and beginning of May following, from the same nursery stock in the same way as formerly, and not one case of failure amongst these plants resulted. A common practice exists of "preparing the tree," which it is intended to transplant. This is a very safe and good precaution. It has hitherto been generally done thus:—The tree having been selected which it is desired to transplant, a trench is dug about 3 feet deep and 2 feet wide, at some distance (say 6 feet) from the stem and around it, and as much under the roots as can with safety be managed, so as to relieve the seat of the tree in the ground, and thus a complete system of undermining is established. This should be done in the autumn or spring prior to removal; or two seasons may be taken, and the trench be dug one-half each year round the roots of the tree; or the trench in question may be dug in the autumn, and again next autumn a similar trench, probably 6 inches nearer the stem, may be dug around the tree. In this way a "fresh growth" of young root fibres is induced, and the removal of the tree with greater safety is ensured. With the teeth of a rake or fork, the earth is next picked away from the ball which envelopes the mass of roots around the stem, until the young rootlets or fibres are reached, when the operation is stopped; fresh loam or virgin sand is added, or a compost applied to the rootlets of well and thoroughly rotted turf mixed with a good addition of lime. The trench thus filled up is then closely packed, so as to keep the fresh soil added firm and close to the points of the rootlets exposed; a turf is then planted on the surface to keep out drought, and the tree is thus left for two seasons, when the process of transplanting is proceeded with, and with much greater certainty of success, owing to the increase of the numerous rootlets which the adventitious mixture of fresh soil has created. In opening the trench round the bole to transplant the tree, care should be taken to dig outside the original line of the old trench of preparation, so as not to disturb the newly

formed spongioles. The tree is then raised out of its position, if large, by the aid of the usual machinery; and if small enough to require only manual labour, by the aid of a few workmen, in which case it may be placed in a box or frame, to support the root-ball upon a hand-barrow, and so transported to its new site with little risk. If some distance has to be travelled, a spring-cart should be employed, and upon no account should a common country cart be used for this operation, for the injury done to the ball surrounding the root-fibres, by its being shaken off, or cracked, will materially effect the success of the removal, from the exposure to which these delicate organs are subjected. So imperative is it to preserve from the action of the air these tender parts of the tree, that a further precaution may be advantageously adopted, which is, in removing with a spring-cart, to have the hand-barrow carried or borne by two labourers seated in the cart—thus not allowing the handspokes or bearers to rest on any part of it, and thereby taking any jolting of the springs, when going over uneven ground, entirely off the hand-barrow bearing the ball. In most instances the root-ball will be sufficiently large and heavy to resist the action of wind upon the tree, and to keep it steady and secure in its place without any props. Various modes of securing it, however, against wind, are frequently adopted; the best of which is simply to moor the tree by stays of rope or strandwire to stakes fastened into the ground. We have seen stobs driven into the earth quite to the head, at the four corners of the ball, and cross planks nailed to these, so as to steady the root and ball, but we think the rope-moorings preferable. Before placing the tree in its new situation, a drain should be cut from the bottom of the pit, at least 6 feet in length, from the drop of the branches, and filled in with broken stones, or loose coarse gravel, whereby the superabundant moisture is carried away from the young fibres; and they consequently enjoy greater warmth and equality of temperature, and thus become more vigorous and healthy. In transplanting from tubs or pots, it is well to wash out all the roots well, and free them from their pot-bound habit, puddle them, when damp, in fine pulverised dry tufty-loam, and in transplanting, spread out all the roots regularly and equally on all sides, upon a mound or rounded surface made at the bottom of the square pit in which the plant is placed. This hole, in the case of ordinary specimens of about 3 feet high (if Coniferous trees or evergreen shrubs), need not be deeper than 1 foot from the surface. Even in windy situations, and in sheltered spots, most of the Conifers may be planted (according to the kind) with their roots almost on the very surface of the ground, raising a mound on the top. In damp soils this mode we find very suitable. In the process of preparation referred to, injury is sometimes done to the tree. It happens that, in digging the trench, many roots (if the specimen be large) are cut, and the tree thus suffers as much as if it had really been transplanted, and when, two seasons afterwards, it comes to be removed, its system suffers a similar disturbance again. To prevent this, we prefer the mode of digging, in one season, only round one-half of the tree roots, and, in the following autumn, completing the preparatory process, by cutting round the others, and so removing the plant the third year. By this precaution the whole system of the tree does not receive such a shock or sudden check at once, but is prepared by a gradual process for its change of site.

Baring the Roots before Transplantation.

Another method of transplantation is sometimes employed, and, where it can be carefully accomplished, is a very good one. Instead of "preparing" the tree (this system is not so applicable to very large specimens) its roots are bared to their very points, by stirring the soil in their proximity, in the first instance, with "grapes" or forked spades, and removing it carefully, by gradually forming a trench considerably away from the bole of the tree and around it, as indicated in the former method described, only at a wider circumference, so as to embrace every minute rootlet, and thus gradually working inwards and around, and under the trunk, till all the rootlets and large roots also are relieved and carefully secured, when the tree is at once quickly removed to a large deep and wide pit previously prepared for it, and in which the root-fibres are arranged and disposed very regularly, fresh soil and compost of well-rotted turf being added, and firmly packed till the hole is completely filled up. In this case, secure protection from wind is necessary by using either stays or stakes; and a further security to the stability of the tree, is to splice to its roots long pieces (12 to 20 feet in length) of thick roots, from 2 to 3 inches in diameter, cut from other trees. These, when well earthed up, being buried with the roots of the specimen, act as excellent underground anchors to the tree, and serve to moor the loosened roots more securely in their lateral directions, and enable them to resist the strain of the head against the wind. In every instance after removal, all useless growth of small twigs from the stem should be pruned away, to prevent unnecessary waste of sap being appropriated to their development instead of being

thrown into the nourishment of the head of the tree. Having thus considered the subject of transplanting in general, the season and circumstances best suited for the various species and the many precautionary measures to be observed in the process; and having also glanced at the methods usually employed in removing large specimens, and the sizes most to be recommended for the purpose, it would be improper, before concluding, to omit mentioning the immense success in this department of landscape gardening achieved by the late Sir Henry Seton Stewart, of Allanton (the Evelyn of his day), with the aid of the machinery devised by himself, of which the implements used now-a-days are but slight modifications and improvements. Indeed, of the art of removing, successfully, large trees, and of so "creating real landscape," as he has himself styled it, he may be regarded as the pioneer. Nor need we refer to the labours and improvements upon the previous methods and machinery employed by Brown, the intelligent practical forester, whose name and fame in this department also will be coeval with the existence of his favourite trees. On all sides, where the labours of these two leaders in arboriculture were achieved, their footprints may still be traced in the living monuments of their skill and success—thus placing the art upon well-defined and properly understood principles. Nor should we forget to notice the carefully devised and successfully executed efforts in the same direction of the late Mr. William M'Nab, as evinced in many of the present denizens of the Edinburgh Botanic Garden, several of which were, in 1822, removed, when of large size (many were from 37 to 43 feet in height), from the site of the old Botanic Garden, to the present one, a distance of about a mile and a half! In fact, the machinery as used in some cases nearly half a century ago, must still be the means employed, if trees of very large magnitude are to be removed, or the operations of transplanting are to be carried on upon such a scale as Stewart, Brown, M'Nab, and a few others have pursued. But upon this scale we wish ever to see transplanting exceedingly limited; for, although perfectly successful, the comparative cost of lifting a tree from 30 to 40 feet high, and one of only 6 to 10 feet in height, and their comparative progress afterwards, is upon the one hand of expense too wide, and upon the other of result too close and insignificant to lead to the belief or desire, that very large trees should ever be generally transported from place to place, or that it is economical and advantageous to do so. For immediate landscape effect, no doubt the larger the tree the better, and those who desire to anticipate years of growth and progress must employ such means to attain their object, but they must at the same time make up their minds to the labour and cost of such dearly-bought pleasure, and to the risk of failure to be run in attaining it; while, on the other hand, those who are content with less straining after immediate effect, and merely transplant specimen trees from about 6 to 10 feet in height, will be amply rewarded in a very few years by superior permanence and enduring results in the timber trees they have planted, and by the present satisfaction of witnessing their strong and healthful growth, and rapid progress, as well as by the knowledge of the eventually enhanced value they are conferring upon their estates.—*Transactions of the Scottish Arboricultural Society.*

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Preserving Timber: L. T. There is no doubt that creosote is the best preservation against Fungus. It is also a capital preservative against the attacks of time on fences and all exposed wood-work.

Arbutus coccinea.—Can anyone tell me where I can obtain a plant of this Arbutus? I am told that it is very handsome. I have A. Crooni, which is now covered with clusters of pretty flowers, that contrast well with the bright green foliage.—J. B., *Southampton.*

Haws on the Double Scarlet Thorn.—I have a double scarlet Thorn in my nursery bearing Haws almost as freely as the single variety, and they are nearly twice the size of ordinary Haws and rather flattened in shape. Do double-flowered Thorns frequently fruit? I have not heard of them doing so before.—W. RUMSEY, *Waltham Cross.*

Cistus tauricus.—This is a gem among hardy shrubs. It grows about 1 foot or 18 inches high, and has a neat compact habit. The stems and branches, as well as the leaves, are clothed with short hoary down. The flowers are produced singly on short stalks, and are about 2½ inches across and of a bright rosy-purple. It flowers in June, July, and August. For the margins of shrubberies, or forming beds of rock-roses in suitable spots, it is one of the handsomest of its class, and there is no more desirable rock-work plant. It is easily increased in autumn by means of cuttings inserted in sandy soil in a cold frame or under a hand-glass.—*The Gardener.*

Raising Seedling Plane Trees: B. S. The following extract from Grigor's "Arboriculture" will help you:—"In Britain, the tree is sometimes grown from seeds, that are produced in round balls, which should be broken, and the seeds sifted, to separate them from the cottony substance with which they are mixed. They should be sown in March. They require scarcely any cover of soil, but should be pressed into the surface of the ground, and kept moist by being covered with leaves or spray of trees. But the most speedy method of propagation is to grow the plants by layers, in a similar manner to that recommended for the Lime tree." The trees planted in London are, for the most part, raised in French nurseries.

LAMPS FOR GARDENERS' USE.

For night-visits to hothouses, the gardener should have good lamps, and therefore we do not hesitate to allude to two which have been sent to us for testing, and which appear to possess uncommon merit. The first is called the Hurricane lamp, which gives an excellent light, and cannot be put out by the strongest wind. It burns brightly and steadily for twenty hours, at a cost of less than a farthing an hour. To those having suburban gardens, with out-houses or stabling, it would seem to be valuable. The other lamp is the Paragon, introduced, like the preceding, by Messrs. Dietz, and is an excellent lamp for ordinary purposes. This was submitted to a careful test with various other good lamps by the editor of the *Field*, and by him declared to be the best lamp he had tried. Not least among the minor advantages of construction in these Paragon lamps is one whereby their durability is greatly extended. Everybody using lamps knows how apt people are, in taking the burners off to get at the reservoir, to injure the pin, so that the toothed wheels cease to act in perfect unison, and are irregular, and thence a wasteful flame results. With this lamp there is no need to remove the burner except when a new wick is wanted—once in five or six weeks. By raising in the flat top of the burner a little trap door, access is at once obtained to the reservoir, which can thus be filled without removing the burner, which consequently lasts much longer, and by shaping its upper edges to a slight convexity the flame is found in practice to be wholly prevented from drawing upwards into long and irregular tongues, as is too common with other lamps. These lamps are suited for burning petroleum or mineral oil, which is obtainable, of excellent quality, at 2s. per gallon. There exists a wholly unfounded prejudice against oil of this kind, which is frequently supposed to be unsafe. No respectable tradesman now sells petroleum whose vapour will take fire under 130° Fahrenheit,

The Hurricane Lamp.

Paragon Lamp.

and as neither of these lamps will raise the oil in their reservoirs, if of glass or china, above 70° or 80° Fahrenheit, even in summer that danger is, with the most ordinary care, absolutely got rid of. When metal reservoirs are employed, some non-conductor should be interposed between them and the burners. Under no ordinary circumstances can petroleum be raised to blood heat, and even at that temperature there is a margin of from 20° to 30° Fahrenheit before it is more liable to combustion than colza oil or any other of our common vegetable oils; while it is not nearly so liable to take fire as brandy, the vapour of which ignites in the same manner at a much lower temperature. The light afforded by the Paragon lamp, we may add, has been satisfactorily proved to equal in brilliancy that of no less than twenty-eight sperm candles.

FLOWER PAINTING AT THE FEMALE SCHOOL OF ART.

It is always interesting to flower lovers and horticulturists to see how the products of their flower beds, and of their flowering shrubs, are treated by those artists who aspire to reproduce their beauties on canvas or paper; and every true lover of floral beauty must have been highly gratified to witness the general success with which the young lady artists of the institution in Queen Square have acquitted themselves in the elegant portraiture of their exquisitely beautiful "sitters," if we may be permitted the use of that somewhat technical term. Most, if not quite all, of the subjects selected and grouped by the lady professors as models for their pupils have been well chosen and placed together with much taste. Among the most ambitious of these essays in flower painting are the

works of Miss A. E. Hopkinson, who has executed, with very considerable skill, a group composed of masses of intermingled Primroses and Blue-bells, on a mossy bank. Her Primroses have the fresh, clear aspect of the first flower of spring; and are beautifully painted, while a branch of Apple, in full bloom, also intermingled with the composition, after a very tasteful fashion, is reproduced with extreme delicacy, and with a bright and sensitive feeling for floral colour. Miss Hopkinson has also a good study from a group of autumn foliage—Blackberry-brambles, with their fruits, and a few sprigs of finely berried Bryony. The tinting of the foliage is gorgeously rendered; and the purple-black of the Blackberry, and scarlet of the Bryony berries, more or less intense in proportion to their ripeness, are executed with an appreciative care that is highly creditable, as bearing testimony to the correct studies by which alone the young artist can have attained her present proficiency. The next composition which attracted my attention was, perhaps, equally good. It was an ambitious group, formed by an entire plant of *Orchis maculata*, a gush of Primrose bloom, and, on the same rooty bank, a thrush's nest, with eggs, seemingly just left there by some juvenile nest-robber, while in pursuit of other depredations of a similar kind. The *Orchis* is boldly and fairly painted in outline, colour and treatment; and the Primroses also, though not quite so good; but the painting of the thrush's nest is not nearly equal to the rest of the picture. Want of cleanness and purity of colour is one of the most common defects of young painters; but Miss Emily Austin, the paintress of this highly meritorious composition, evidently possesses qualities that will rapidly carry her far beyond the more common errors of all beginners. Another composition by this young lady already shows, indeed, that multicaess of tone will not remain a permanent defect in her style. It consists of a group of the more vividly-coloured Fungi, which appear to be growing naturally among Moss and Lichens, and the dazzling scarlet hues of some of them are rendered with very great clearness and brilliancy. Such a composition would make a striking foreground to a large picture. Miss Ellen Hancock has a group of autumn-tinted Ferns, growing on a mass of rock, combined with some autumn foliage, in its livery of crimson, purple, and gold. This is a much better picture than the same young lady's White Lily and *Gladiolus*. Miss Alice Lock has been more fortunate in her treatment of the *Gladiolus*; her selection of five varieties of which has been made to form a good composition, grouped with *Arbutus* branches covered with bloom. A group of brilliant *Pelargoniums*, with *Tournefortia* Tulips and white *Spiraea japonica*, and a grand raceme of blue *Wistaria* lying carelessly in front, is also the work of Miss Alice Lock, and must rank among the best compositions in the room; the low baskets of unbarked wicker-work in which the flowers are placed is well treated, and, with a little more crispness and largeness of touch, and a somewhat fuller tone of colour, would have been excellent. Miss Jessie Corcoran has a pretty composition of Wild Roses and other objects, very nicely drawn, and crisply and cleanly painted, with the exception of the eggs in a chaffinch's nest in the foreground; which are far from having all the translucent purity of tone required. Those who recollect Hunt's inimitable nest and eggs, are, perhaps, hard to please. Her separate studies of Iris, *Gladiolus*, and *Dielytra*, are exceedingly conscientious, and so far meritorious, and they will have given her a knowledge and power of outline which must become of great advantage to her in future work; but we must remark, that the *Dielytra* has either been painted from a poor specimen, or the artist has not fully appreciated the robust, yet elegant, luxuriance of the plant, or the proudly bowing habit of its leading racemes of bloom. Among smaller sized compositions, Miss E. Hancock's group of white and rose Azaleas and Miss Austin's pretty group of semi-double Blush Roses may be pronounced really beautiful studies, showing that either of these young ladies might at once be safely trusted with the artistic representation of the botanical aspect of plants. In the department for water and chalk drawing, there are several interesting specimens of good work. The nobly sculptured group of the Egg-plant, forming a portion of Ghiberti's marvellous foliaged border, running, in high relief, round the architrave of his famous door of the Baptistery, at Florence, which Michel Angelo pronounced worthy of being the entrance to Paradise, appears to be a favourite model at the female school of art. There are several copies in chalk, all good, but one remarkably excellent. Among the water-colour studies of single flowers, with applications of their leading outlines to ornamental pattern work, many are very successful. The reduction of the main lines of the Snapdragon flower to the purpose of forming a semi-geometrical pattern, is especially ingenious; and the analysis and application of the flower of the Winter Aconite to a similar purpose, perhaps, still more so. But one of the most remarkable drawings in the room, is an outline drawing of some grand sprays of Bramble with its fruit. It is the work of Miss Adelaide Heston, drawn in competition for the Gilchrist scholarship of £50.

WESTBOURNE.

THE MOUNTAINS AND THEIR WORK.

It may not, even at this day, be altogether profitless or unnecessary to review briefly the nature of the three great offices which mountain ranges are appointed to fulfil in order to preserve the health and increase the happiness of mankind. Their first use is, of course, to give motion to water; every fountain and river, from the inch-deep streamlet, that crosses the village lane in trembling clearness, to the massy and silent march of the everlasting multitude of waters in Amazon or Ganges, owes its play, and purity, and power, to the ordained elevations of the earth. Gentle or steep, extended or abrupt, some determined slope of the earth's surface is of course necessary before any wave can so much as overtake one Sedge in its pilgrimage; and how seldom do we enough consider, as we walk beside the margins of our pleasant brooks, how beautiful and wonderful is that ordinance of which every blade of Grass that waves in their clear water is a perpetual sign; that the dew and rain fallen on the face of the earth shall find no resting place—shall find, on the contrary, fixed channels traced for them from the ravines of the central crests down which they roar in sudden ranks of foam to the dark hollows beneath the banks of lowland pasture, round which they must circle slowly among the stems and beneath the leaves of the Lilies; paths prepared for them, by which, at some appointed rate of journey, they must evermore descend, sometimes slowly, sometimes swiftly, but never pausing; the daily portion of the earth they have to glide over marked for them at each successive sunrise, the place which has known them knowing them no more, and the gateways of guarding mountains opened for them in cleft and chasm, none hindering them in their pilgrimage; and, from far off, the great heart of the sea calling them to itself. The second great use of mountains is to maintain a constant change in the currents and nature of the air. Such change would, of course, have been partly caused by differences in soils and vegetation, even if the earth had been level: but to a far less extent than it now is by the chains of hills, which, exposing on one side their masses of rock to the full heat of the sun (increased by the angle at which the rays strike on the slope), and, on the other, casting a soft shadow for leagues over the plains at their feet, divide the earth not only into districts but into climates, and cause perpetual currents of air to traverse their passes and ascend or descend their ravines, altering both the temperature and nature of the air as it passes in a thousand different ways, moistening it with the spray of their waterfalls, sucking it down and beating it hither and thither in the pools of their torrents, closing it within clefts and caves, where the sunbeams never reach, till it is as cold as November mists; then sending it forth again to breathe softly across the slopes of velvet fields, or to be scorched among sunburnt shales and grassless crags; then drawing it back in moaning swirls through clefts of ice and up into dewy wreaths above the snow-fields; then piercing it with strange electric darts and flashes of mountain fire, and tossing it high in fantastic storm clouds, as the dried Grass is tossed by the mower, only suffering it to depart at last when chastened and pure, to refresh the faded air of the far off plains. The third great use of mountains is to cause perpetual change in the soils of the earth. Without such provision the ground under cultivation would, in a series of years, become exhausted, and require to be upturned laboriously by the hand of man; but the elevations of the earth's surface provide for it a perpetual renovation. The higher mountains suffer their summits to be broken into fragments and to be cast down in sheets of massy rock, full, as we shall see presently, of every substance necessary for the nourishment of plants; these fallen fragments are again broken by frost and ground by torrents into various conditions of sand and clay—materials which are distributed perpetually by the streams farther and farther from the mountain's base. Every shower which swells the rivulets enables their waters to carry certain portions of earth into new positions, and exposes new banks of ground to be mined in their turn. That turbid foaming of the angry water—that tearing down of bank and rock along the flanks of its fury—are no disturbances of the kind course of Nature; they are beneficent operations of laws necessary to the existence of man and to the beauty of the earth. The process is continued more gently, but not less effectively, over all the surface of the lower undulating country; and each filtering thread of summer rain, which trickles through the short turf of the uplands, is bearing its own appointed burden of earth to be thrown down on some new natural garden in the dingles below. And it is not, in reality, a degrading but a true, large, and ennobling view of the mountain ranges of the world if we compare them to heaps of fertile and fresh earth, laid up by a prudent gardener beside his garden beds, whence, at intervals, he casts on them some scattering of new and virgin ground. That which we so often lament as convulsion or destruction is nothing else than the momentary shaking of the dust from the spade. The winter floods, which inflict a temporary devastation, bear with them the elements of succeeding

fertility; the fruitful field is covered with sand and shingle in momentary judgment, but in enduring mercy; and the great river, which chokes its mouth with marsh, and tosses terror along its shore, is but scattering the seeds of the harvests of futurity, and preparing the seats of unborn generations. I have not spoken of the local and peculiar utilities of mountains; I do not count the benefit of the supply of summer-streams from the moors of the higher ranges—of the various medicinal plants which are nested among their rocks; of the delicate pasturage which they furnish for cattle; * of the forests in which they bear timber for shipping; the stones they supply for building, or the ores of metal which they collect into spots open to discovery, and easy for working. All these benefits are of a secondary or a limited nature. But the three great functions which I have just described, those of giving motion and change to water, air, and earth, are indispensable to human existence. They are operations to be regarded with as full a depth of gratitude as the laws which bid the tree bear fruit, or the seed multiply itself in the earth. And thus those desolate and threatening ranges of dark mountains—which, in nearly all ages of the world, men have looked upon with aversion or with terror, and shrunk back from as if they were haunted by perpetual images of death—are, in reality, sources of life and happiness far fuller and more beneficent than all the bright fruitfulness of the plain. The valleys only feed; the mountains feed, and guard, and strengthen us. We take our ideas of fearfulness and sublimity, alternately, from the mountains and the sea, but we associate them unjustly. The sea wave, with all its beneficence, is yet devouring and terrible; but the silent wave of the blue mountain is lifted towards heaven in a stillness of perpetual mercy.

RUSKIN.

USES AND DISTRIBUTION OF THE POKEBERRY.

(PHYTOLACCA DECANDRA.)

This is believed to have various important medicinal properties, and its ripe berries are used, or said to be used, for colouring wines—a property which De Candolle seems jocularly to hesitate whether to reckon as an evil or a good; for, as he says, if it is hurtful to the purchaser, it is profitable to the seller. Its leaves are extremely acrid; but the young shoots lose this property by boiling in water, and are eaten in the United States as Asparagus, and in soup in Russia. It is by some considered likely to be very useful as a covert plant, as pheasants are said to be fond of the berries. It is also a vigorous perennial, desirable for grouping with the stouter herbaceous plants. It is a plant of some importance in gardens, and therefore the following interesting notes, communicated by Mr. Andrew Murray to the *Field*, may have some interest for our readers. It is an American plant, like all the species of *Phytolacca*, but it is also met with in the Old World, and more familiarly in the south of Europe, where it is supposed to have been introduced. De Candolle gives, in his "*Géographie Botanique*" (p. 736) the following account of its distribution:

Origin, North and South America. It is said to have been imported into the south of Europe some 200 years ago, and that it was cultivated for the purpose of colouring the Bordeaux wines, and also in the gardens of the convents. M. Moquin writes me; "Herborising, in 1843, in the Western Pyrenees, I found several plants of that species in a locality almost desert. But the peasants showed me, at a short distance, the ruins of a convent." Barrelier had seen it in Europe about the year 1650, but he does not say whether it was cultivated or spontaneous. Ray, in 1693, and Linnaeus do not speak of it but as an exotic, cultivated. The name of American Grape, which it bears, confirms this. It is not possible that so remarkable a species could have been passed over by the old botanists. Gouan indicated it as spontaneous near Narbonne in 1765, Haller in the north of Italy in 1768, and a little later Allioni called it wide-spread. The names of "*Uva turca*" or "*di Spagna*," given to it in Italy, suggest that the plant might have spread at first through Barbary or Spain. In 1785 Sibthorp doubted whether or not it was really spontaneous in Greece. It has spread since as far as the inhabited places in the mountains of Armenia (C. Koch, *Linn.* xxi., 736).

Such was the state of our knowledge up to a few months ago. If it is really an introduced plant from America, it stands in a very restricted category, there being only three other American plants which have become at all widely spread by naturalisation in Europe, viz., the *Opuntia ficus-indica*, and *Amarantus albus* in the south, and *Erigeron canadensis* in south and mid Europe. The question of its naturalisation has, however, had fresh light thrown upon it lately by M. Jean Van Volxem, of Brussels. That gentleman attended the floral festivities at St. Petersburg in 1869, and, with his old spirit of travel, extended his excursion to the Caucasus. He there met with the *Phytolacca decandra* under conditions which seemed to him more indicative of a spontaneous origin than of naturalisation. On his

* The highest pasturages (at least, so say the Savoyards) being always the best and richest

return he privately mentioned the fact to me, knowing I was interested in questions of geographical distribution. Since then he has received some additional information, which he communicated to the *Belgique Horticole* in a short notice in July last. He there says:

I have received from a correspondent in the Caucasus, M. Mikosievitch, a rather interesting note for geographical botany. In a letter which I wrote him in 1870, I told him incidentally that I had been surprised to find, very abundantly, in the depths of the forest of Kakhetie, the true *Phytolacca decandra*, which we call "Raisnier d'Amérique," and which we consider a native of the New World. He writes me an answer, that "the *Phytolacca decandra* is called in Lesghien Teho-teho-baha. The Lesghies say that it existed in the country before them. They infuse a morsel of its roots in water for twenty-four hours, and take some drops of that infusion, which is as good a cure for fever as quinine. It stops nausea, and even vomiting. The Armenians make spirits of wine of its fruit. The Georgians call it 'Imerouli saperawi,' and employ it as you tell me they do in the south of France, to give a fine colour to red wine. The Russians call it 'Pampros' (without doubt a corruption of the Georgian name), and use the young shoots when about a foot in height to make their national soup called Borszez (a kind of green soup). I think that, if this plant was a native of America, the people of the Caucasus, still so little advanced in civilisation, would not each of them have given it a different name, nor found so many different uses for it."

Mr. Van Volxem concludes by reminding the reader that the Lesghiens or Avares inhabit Daghestan on the north flank of the Caucasus, while the Georgians occupy Kakhetie on its south flank. This notice has brought out yet another interesting contribution to the history of this plant from the pen of M. Alphonse De Candolle. It appears in the December number of the *Belgique Horticole*, and is as follows:

At the very moment when I was reading the interesting article of M. Van Volxem in the *Belgique Horticole*, on the origin of *Phytolacca decandra*, I received from the interior of China a very curious opuscul which supports the view of the Asiatic origin, or more precisely of a great antiquity on the Asiatic continent, of that American species. M. Karl Koch found it in the inhabited parts of the Caucasus, and of the mountains of Armenia. As its berries are probably transported by birds, and the species in any case has spread rapidly throughout the south of Europe since the discovery of America, I had thought that the plants observed in the Caucasian region were the result of no very ancient transport.

If I may interrupt the passage here, I would wish the reader to observe that I have above given, in my quotation from the "Geog. Bot." of M. De Candolle, all the grounds on which he considers it proved that the plant spread rapidly in the south of Europe after the discovery of America; and he will remark that they are all negative, and resolve themselves very much into this, that the plant is not noticed by the more ancient botanists, while it is said by those who wrote about the middle and end of the seventeenth century to be then widely spread. M. De Candolle goes on as follows:

M. Mikosievitch, in citing the names of the Lesghien and Georgian languages, furnishes an argument in favour of an Asiatic origin. It would, nevertheless, be singular that a species so fitted for rapid extension should have remained in Asia without spreading itself into the south of Europe before the discovery of America. Its nativity in the New World is, moreover, not in the least disputable; and, as there are very few phanerogamous plants common to the temperate regions of the Old and New World, we must rather suppose an already ancient extension from America into Asia. The Chinese documents would support this view. The work of which I speak has been published at Foochow in 1870 by Dr. Bretschneider, physician to the Russian legation at Peking. It is an opuscul, in 8vo, of fifty-one pages with seven double plates, done in English, and entitled "On the study and value of Chinese Botanical works, with notes on the history of plants," &c. The author has replied in a very happy manner to the demand that I had made in my "Géographie Botanique," that the ancient Chinese works should be studied to ascertain the presence in the Empire of China of certain species, spontaneous or cultivated, from a very remote epoch. The information which he gives from works, the oldest of which goes back to the year 2700 before Christ, generally confirms what the other indications had led me to presume regarding the origin of several species. As regards *Phytolacca* there is an interesting observation. The *Materia Medica* of the Emperor Shenlung, of the year 2700 B. C., contains a figure and a description of a true *Phytolacca*, of which it is impossible to say whether it is the *decandra* or the *octandra*. Both are cultivated at Peking, and the roots are employed medicinally by the Chinese. The ancient name is "Shunglu." It may be that the species has been transported by birds from North America or the Sandwich Isles, where Meyen found it, into China at a very ancient epoch, and that from thence it has spread itself from the East to the West, towards the Caucasus; while its introduction from America to Europe would be made later. All the species of *Phytolacca* being American, this hypothesis appears reasonable.—*Belg. Hort.* 1871, p. 354.

It is very probable that in regard to this particular species M. De Candolle's explanation of the mode of its occurrence in both the Old and the New World may be correct; but we must bear in mind that other closely allied plants and animals occur in both, whose presence cannot be so easily explained, and for which, as it appears to many, nothing but former continuity of land, in some point or other, can account.

THE HOUSEHOLD.

Grape Jelly.—Put the Grapes in a jelly pan with a very little water; simmer on the fire till quite soft; then strain through a colander or flannel bag; when the juice is all run out, measure, and allow fully one pound of loaf sugar to every pint of juice; boil till it jellies; when it has boiled twenty minutes, try a little in a saucer. It should be watched for fear of boiling over.

Apples and Tapioca.—Peel four or six good-sized Apples, take out the core, and fill up the cavity with sugar and powdered cinnamon, putting a small piece of butter on the top of each. Place them in a baking dish, and strew round them about a cupful of tapioca (raw) mixed with sugar and some grated Lemon rind; fill the dish with water, and put in a gentle oven until both Apples and tapioca are done.

Apple Snowballs.—Pick and wash well $\frac{3}{4}$ lb. of rice, boil it in plenty of water for a quarter of an hour, then drain and let it cool. Pare and core (but without dividing them) half-a-dozen large Apples, enclose them in the rice separately, tie them in small cloths made the proper size, and boil them for one hour; when eaten, a little butter and sugar will improve them.

Apple Ginger.—To 4 lb. of Apples have 4 lb. of sugar, one quart of water, and 2 oz. of best essence of ginger. First pare the fruit, cutting out every particle of core; then shape it to resemble the small kind of preserved ginger. Boil the sugar and water nearly twenty-five minutes until it is a nice syrup, then put in the Apples; be sure not to stir them much; add the essence of ginger (if 2 oz. be not sufficient, add more). It will take nearly an hour to boil, until it becomes yellow and transparent. There will be some pieces that will not clear; put them by themselves, as they will spoil the look of the rest. It will require skimming. American or Ribston Pippins are best.

German Apple Pudding.—Butter a pie-dish, and lay in it a layer of bread crumbs, then a layer of good cooking Apples pared and quartered, then a layer of good brown sugar, then a very thin layer of finely-chopped suet or little bits of butter, then a layer of bread crumbs, and so on until the dish is filled, taking care to have crumbs at the top. Bake the pudding in a moderate oven for three quarters of an hour. Before serving, sift sugar on the top.

Tansy Pudding, Baked.—Beat four ounces of blanched Almonds very fine in a mortar; add a little Orange-flower water to prevent its oiling. Pour a pint of boiling hot cream upon a sliced French roll; whisk four eggs, mix them with some sugar, a little grated nutmeg, a glass of brandy, and a very small quantity of Tansy and Spinach juice to give it a green colour. Beat a quarter of a pound of butter to a cream, add the Almonds, roll, and other ingredients well mixed together. Beat them for five minutes, lay the mixture in a tart-dish edged with a rim of very light paste, cover it with a top crust, and bake for forty minutes.

Cocoa-nut Pudding.—Break the shell of a moderate-sized Cocoa-nut, so as to leave the Nut as whole as possible. Grate it after removing the brown skin, mix it with 3 ounces of powdered loaf sugar and half-an-ounce of Lemon peel, and add two eggs well beaten. Mix the whole with milk, and put it into a tin lined with puff paste. Bake it a light brown.

Tomato Ketchup.—When Tomatoes are very ripe, slice them and put a layer into a jar; sprinkle salt over it, and lay in another layer; do this till the jar is full; stir them now and then for three days, and let the jar stand in a warm place; they must then remain for twelve days without being stirred, and a thick scum having gathered over them, squeeze the juice from the Tomatoes, and boil it with the same proportion of spice that is allowed for Mushroom ketchup; when cold, bottle it, and seal the corks. In three months strain and boil it again with fresh spice. It will then keep good a twelvemonth.

Cooking "Greens."—Every housewife thinks she can cook "Greens." It is the simplest of all dishes; and yet, in most cases, they are not well served, for much depends upon the manner in which they are boiled. The water should be soft, and a tablespoonful of salt added to a large-sized pot of it, which should be boiling hot when the Greens are thrown in; and then it should be kept on the boiling gallop, but uncovered, until they are done, which can be told by their sinking to the bottom of the pot, and they should be skimmed out as quickly as possible into a colander, so that all the water will run out. Press them with a small plate, then turn upon a platter, add a large piece of butter, and cut up fine. Serve while smoking hot.

Potatoes a la Duchesse.—The following is the receipt of a good cook in a private family in Paris:—Take five middle-sized cold boiled Potatoes, grate and mix them with five dessert-spoonfuls of flour and a half-penny worth of milk, adding to the mixture two eggs well beaten up; prepare a panful of boiling fat, and drop spoonfuls of the paste into the fat, taking them out the instant they have acquired a delicate golden brown colour. With moderate care Potatoes thus cooked are delicious.

FRUITING OF THE MANGO IN PORTUGAL.

His Majesty King Don Fernando, a year ago, had a few plants of *Mangifera indica* planted out of doors in his garden at Necessidades; these plants looked pretty well last spring, nevertheless I must confess that I did not expect much good would result from them. During the King's absence from Lisbon for the summer months, I paid but one or two visits to this charming spot, then suffering much from excess of drought, and, to tell the truth, I completely lost sight of his Majesty's favourites, the famous Mango trees. The greater was my astonishment when Don Fernando informed me, the other day, that one of them was in full fruit, and this astonishment certainly did not decrease when I looked at this phenomenon with my own eyes. The fruiting plant is apparently quite young, not over three or four years of age, showing a height of 1½ metres, more or less, and it bears nine oval-shaped fruits of a duck's-egg size. Being well sheltered against rainy and stormy weather, and not having anything to fear from frost, or even cold, I dare to hope that his Majesty will soon have the pleasure of seeing a dish of ripe Mangoes on his dining table. That Mangoes fruit and ripen very often in Madeira, and even in St. Michael's, is commonly known; but in Continental Europe I believe it will be the first time that such an event has taken place. The Mango has fruited already in one of the stoves of Syon House, if I am not much mistaken, but here, in Necessidades Gardens the tree has developed its fruits under the blue but arid sky of Lisbon, and this deserves well to be reported, with large letters, in the annals of horticulture, as it gives us a new proof of what great success acclimatisation, skillfully managed, may obtain in some of the most favoured spots of southern Europe.

The introduction of the Abyssinian *Musa Ensete* was certainly one of the finest gifts which European gardens have, of late, obtained from foreign countries. A great many of our readers will remember the beautiful specimen of it, which, for many years, was one of the chief ornaments in the Palm-stove at Kew, its leaves being upwards of 20 feet long, and traversed by a stout vivid red rib, while the trunk attained a circumference of 9 feet in three years. But, though this plant may be destined to make one of the most remarkable features in the larger conservatories of northern countries, I incline to believe that its singular beauty will still be far more appreciated in the sunny south. Only a few months ago the King, Don Fernando, had a young *Musa Ensete* planted out in his gardens, and it is quite wonderful to see what dimensions it has reached in this short time. It measures already 4 metres in height, with a stem of about 4 feet in circumference, and leaves of 10 feet in length, more or less. Meeting with all necessary facilities for a vigorous growth, it will, I dare say, soon make one of the finest specimens of its kind in Europe.

Before concluding, I should like to draw attention to a splendid *Cocos australis*, which, though it is one of the most majestic Palms in these gardens, was unfortunately forgotten in my first report, and certainly his Majesty was quite right to complain of this omission. Its quite erect trunk of 2 feet in circumference measures from 40 to 50 feet in length, bearing at its top a profusion of dark-coloured leaves. If Necessidades Gardens excel in beautiful Monocotyledons, those of Penna, with the damp atmosphere of the Cintra Mountains, show other not less attractive features of the vegetable kingdom. Large collections of rare Conifere, Australian Myrtaceæ, Camellias, Rhododendrons, and Azaleas, and especially of strong and healthy Tree-Ferns abound here; and, when I paid a visit to this charming spot, it was difficult for me to decide whether to give the preference to these rare exotic plants, or to the dense thickets of Oaks and Beeches, which reminded me of "dear home."

EDMUND GOEZE.

Lisbon.

The Royal Berks Root Show.—At Messrs. Sutton's root show, which took place on the 21st inst., Mr. Goodey, gardener to C. R. Littledale, Esq., of Scarlett's Park, Twyford, Berks, exhibited an enormous round Squash, of a dull buff-yellow colour, and handsomely netted, measuring about 7½ feet in circumference, and weighing 168 lbs. At the same exhibition, Mr. Tegg, gardener to Mr. Walter, M.P., was awarded a handsome silver cup for a superb collection of twelve varieties of vegetables of first-rate quality, and neatly arranged. The second prize was won by Mr. Higgs, gardener to Mrs. Crawshaw, of Caversham Park, Reading; and the third by a well-known grower, Mr. Pragnell, of Sherborne Castle. Of Potatoes no fewer than twenty-three collections were exhibited, the silver cup offered for which was awarded to Mr. W. Wildsmith, gardener to Lord Eversley; Mr. McKinlay, of Beckenham, Mr. Higgs, of Caversham, and Mr. Johnstone, of Savernake taking prizes in the order in which their names stand. The competition for twelve tubers of Red-skin Flour-ball was remarkable; nearly fifty dishes being exhibited, some of which were of great size, the twelve largest weighing about 26 lbs. The first prize in this class was awarded to Mr. Stollery, Railway Inn, Staines, his twelve being the handsomest of the kind

we have yet seen. Among other garden produce there were shown some magnificent examples of the Reading Onion, Intermediate Carrots, and Student Parsnips, the exhibition altogether being full of interest and a most complete success.

Messrs. Carter's Root Show.—This took place this year in the Agricultural Hall, which contained a magnificent display of Mangolds, Swedes, Turnips, Potatoes, and numerous other kinds of roots, contributed from all parts of the kingdom, the whole of the articles having been grown from seed supplied by Messrs. Carter. The specimens shown were marvellous examples of what can be produced with good cultivation even during an unfavourable season. The exhibition being wholly of an agricultural character precludes our noticing it in detail. We may, however, say that the specimens of Carter's long red and Carter's Warden globe Mangolds were the largest and most symmetrical we have hitherto met with of these deservedly popular varieties. Although the Turnip entries were not so numerous as the Mangold, yet the classes were well represented, the roots of Carter's Purple-top Mammoth being exceptionally good. All the other classes were also well represented, and the show altogether was most interesting and attractive.

Passe Colmar Pear.—I notice that Mr. Ingram (see p. 474) mentions that this Pear does not deserve all that has been said in its favour. Permit me to say I have grown it both in the midland counties and in the sunny south, and a thirty years' experience of it enables me to bear testimony to its exquisite flavour; and I make bold to say that, after much experience at Arundel, where there is one of the best private collections of Pears grown, and afterwards at dear old Chiswick, where there used to be such a collection as was nowhere else to be found, *Passe Colmar*, taking all its qualities into account, is the best Pear extant; but, to develop its highest qualities, it must be grown on a wall.—R. GILBERT.

A NEW "LEGEND OF THE FORGET-ME-NOT."

WHEN Psyche lost her Lord, the Lord of Love,
Weeping alone she wandered,
Listless by every well-known field and grove,
And on her lost Love pondered.
Lastly by Lethe's stream her footsteps strayed;
And "Oh!" she said, in sighing,
"That I might dip, and my past life be made
Like dreams with daylight dying!"
The big tears from her blue eyes raining down
Fell on earth's pitying bosom:
Sudden there sprang amid the Sedges brown
Blue as her eyes a blossom.
And o'er her head, soft rustling sweet and low,
As though some bird's wing flattered,
In those loved tones whose loss was all her woe,
"Forget-me-not!" was uttered.
No more: no sight, no touch: these words alone:
And "Ah!" she cried, "forget thee?"
Nay, but half Love in our glad life was known;
Half Love to regret thee.
"Forget thee? Nay, these flowers my tears begot
Shall be to me a token
Of Love: they shall be called Forget-me-not,
The name to cheer me spoken."
So well, sweet river-flowers, we welcome you,
Earth with faint sadness scenting,—
Born of the tears from Psyche's eyes of blue,
For her lost Love lamenting.

—Spectator.

PERSONAL.

THERE is a portrait, in the last issue of *Moore's Rural*, of Mr. William Saunders, superintendent of the State Horticultural Garden at Washington, an able horticulturist, and the founder of the remarkable new "Grange" movement in America. Mr. Saunders was elected the first master of the National Grange, which was organised at his office at Washington on the 11th of December, 1867. About the 1st of January, 1868, he issued a circular, "explaining very clearly and forcibly the considerations which had led to the formation of the Order, and its purposes and aims." This circular was widely distributed among cultivators, and undoubtedly exercised great influence, by imparting information concerning its principles and objects, in securing the establishment of the Order and its subsequent remarkable success.—We hear that Mr. James Smith, late of Exton Park, Rutlandshire, is leaving the management of the gardens of Lord Dartmouth, at Patshull, Wolverhampton.—The annual *source* of the workmen in the employ of Messrs. Sutton, of Reading, took place on Monday of last week. A dinner, songs, and recitations were the chief features of the entertainment.—Mr. Thomas Simpson, who, for eight years, has been gardener at Broomfield Lodge, Chelmsford, retires from the management of that establishment at the beginning of next year, and will commence business as a garden architect and market gardener, at St. John's Nursery, Chelmsford.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but

THE ART ITSELF IS NATURE."—*Shakespeare.*

POLLARDING TREES IN SMALL GARDENS.

POLLARDING, or severely cutting in the branches of trees, is not a practice to be generally recommended; still there are instances in which it is found to be absolutely necessary. In many suburban villa gardens the originally planted hardwood trees, such as Oak, Ash, Elm, Beech, Lime, Horse Chestnut, &c., have been allowed to go on increasing for a series of years, frequently interfering with each other, and often rendering such gardens close and unpleasant; nevertheless no reason, however urgent, will induce the proprietor to allow any of them to be removed, perhaps owing to all of them being finely developed specimens. This is a feeling with which I fully sympathise; but for the consolation of those who, from dire necessity, have to part with such specimens, I would offer the following observations. A case has recently come under my notice where some large hardwooded trees standing near a boundary wall, with their tops overhanging a public road, had from necessity to be reduced or removed altogether; reduction was finally resolved on, and carried out during the winter of 1871. The chief trees operated on were Ash, Beech, Wych Elm, and Horse Chestnut. All were wide-spreading trees, and between 40 and 50 feet in height. The largest specimens, at 3 feet above the ground, measured in circumference as follows: Ash, 6 feet; Beech, 5 feet 4 inches; Elm, 8 feet 5 inches; and the Horse Chestnut, 5 feet 5 inches. All were cut down to within 18 or 20 feet from the ground, and portions of the main branches, averaging in length from 3 to 4 feet, were left in such a manner as to give the denuded trees a regular outline; they were then carefully operated upon according to the strictest rules of forestry as regards ornamental trees, all sloping cuts being smoothed and darkened over. During the first year after the operation, standing as they do side by side, they certainly presented, as might be expected, a somewhat bare appearance, which would not have been so much the case if only alternate specimens could have been operated on. After the first year, however, they annually improved, so that now their appearance is really pleasing to the eye, the stumps of the branches left being clothed with numerous young and healthy twigs. During the first year, the Ash made growths 4 feet long, during the second 3 to 4 feet, and during the third about 2 feet. The Elm made from 2 to 3 feet during the first year, 3 to 4 feet during the second, and from 4 to 5 feet during the third. In the case of the Wych Elm it is necessary, in order to secure a tree with a good outline, occasionally to prune in a little the strongest of the newly-made branches, without which it is apt to have a few of its leaders taking a somewhat horizontal direction, to the detriment of the others. The Horse Chestnut averaged growths about 2 feet long during the first year, from 2 to 3 feet during the second, and about 2 feet during the third. The Beech made about 3 feet growth during the first year, but by no means numerous, 1 to 2 feet during the second, and 18 inches during the third. I was rather surprised to see the Beech tree putting out any young twigs at all, as it generally does so with reluctance. It made its largest growths during the first year, a circumstance probably owing to the existence of extra sap then in the stem, the after-growth being much smaller. After the trees had been cut over, and the branches removed, all ought to have received a good coating of fresh soil over the surface of the roots. This would have been the means of greatly improving them, particularly the Beech; indeed, every tree and shrub, when pruned down and reduced, ought to be thus treated, more particularly large evergreen shrubs, which in many cases die from the want of this necessary precaution. This is often observable in the case of large Portugal Laurels, Hollies, and Yews, as, owing to their closeness, the roots are generally near the surface, and liable to be injured by frost or exposure to the sun. I may also remark here that as the bark of the Beech

tree is of rather a hard dry character, it would be much in its favour, after being headed down, to have the stems occasionally syringed, particularly if the weather is at all dry and warm. Although the particular trees alluded to have only been three years cut in, when in foliage, they certainly have, as has just been stated, a very good appearance which warrant our recommending the practice in places where trees would otherwise require to be altogether removed; in some situations, too, only every alternate tree bordering a property would require to be thus pollarded. In the case of Elm trees standing within a boundary wall, I have recommended each alternate tree to be pollarded, and branch-pruned as described, and the result in all cases, where attention has afterwards been paid to them, has been satisfactory, the pollarded specimens filling up in a creditable manner the spaces between the branches of those left untouched. The Lime tree, even when of large size, stands with impunity "topping," and branch cutting, and the Ash, English Elm, Poplar, and Willow, I have often seen so treated and with success. It is well known that the Beech, in a young state, will stand any amount of cutting; but I never recommended large Beeches to be so treated till I observed the progress made by the one referred to. My object in making these remarks is to point out to those individuals who are unnecessarily scrupulous about the thinning of outside trees, that if they can put up with the somewhat bare appearance of them for a short time, such pruned trees in a year or two, if properly cared for, become quite as ornamental even at forty or fifty years of age, as they were when only twenty years old.

Royal Botanic Gardens, Edinburgh.

JAMES McNAB.

DECEMBER FLOWERS IN THE ISLE OF WIGHT.

I PICKED a nosegay this morning in the open air, which seems to me such a strange one for the time of year that I think the best thing I can do with it is to send it to you. It will show you how we can cheat the winter in the Isle of Wight. It is not too much to say that representative plants of every month in the year are in bloom in my garden at this time. I should say that I am indebted to the kindness of Sir William Hutt for the first seven I send you, and to Mr. Gassiot, of St. John's House for about as many more. Sir W. Hutt's garden at Apley Towers will soon be one of the finest in the south of England, and he is making some experiments with flowers and shrubs that are of the utmost interest to every one who cares for them at all. The *Lapageria rosea*, which he has planted against a wall with a west aspect, has at this moment more than 200 blossoms on it. They are such as those which I have sent to you, and nothing could be more beautiful than they are. Also, *Cassia corymbosa* is still most beautiful with him. I am told by Mr. Ellacombe that this fine shrub is very common in Paris in the summer, but it is quite a new thing with us to see it out here in all its glory in mid-winter. If it had not been for the slugs I could have added a fine specimen of *Iris nudicaulis* in the list. *Iris stylosa* has been a kind of harbinger of spring before its time. A deluge of rain which we have had during the last two or three days has done a great deal of damage to our flowers; they were looking much better before it came. *Primula japonica* was in very good form a few days ago. *Stokesia cyanea* is the only one of the flowers I send to you that has not come directly from the open ground. The climate here does everything for us."—W. EWANK, *St. John's, Ryde.*

[The nosegay alluded to was composed of the following materials, all so finely in flower as to more resemble May than December, viz.:—*Arbutum* Duc de Malakoff, *Desfontainia spinosa*, *Cassia corymbosa*, *Lapageria rosea*, *Pimelea Hendersoni*, *Daphne* (two sorts), *Polygala Dalmatiana*, *Iris stylosa*, *Berberis Darwinii*, *Roses* (Banksian and other sorts), *Convolvulus mauritanicus*, *C. Cueurum*, *Iberis gibraltarica*, *Lithospermum prostratum*, *Erica carnea* (and two other sorts), *Clarkia*, *Armeria formosa*, *Achillea aurea*, *Clematis Jackmani*, *Pentstemon* (two or three sorts), *Gazania splendens*, *Dianthus superbus*, *D. hybridus*, *Stokesia cyanea*, *Fuchsia* (three sorts), *Veronica* (two or three sorts), *Erigeron speciosus*, *Anemone coronaria*, *Hypericum calycinum*, *Othoua cheirifolia*, *Lardizabala biternata*, *Schizostylis coccinea*, *Alstroemeria psittacina*, *Hydrangea*, *Coronilla glauca*, tree *Carnation*, *Cyclamen Coum*, *C. Atkinsii*, *Mesembryanthemum*, *Louicea sempervirens*, *Jasminum revolutum*, *J. nudiflorum*, *Ajuga reptans*, *Linum flavum*, *Calceolaria*, *Violet* (Neapolitan and Russian), *Sedum Anacampseros*, *Cheiranthus Cheiri*, *Primula japonica*, *Sapiglossis*, *Coreopsis*, *Vinca major*, *Mignonette*, and *Escallonia macrantha*.]

NOTES OF THE WEEK.

— DR. McNAB is at present forming a British Herbarium at the Royal College of Science, Dublin, and would be glad if any friends would assist him by donations of rare or critical species.

— M. VAN HULLE, of Brussels, states that they grow *Nasturtiums* in Belgian Apple orchards and let them climb up the trees to keep off the American Blight. Also, Tomatoes are planted among the Grape Vines to keep off wasps; it is said that they do so effectually.

— WE understand that Dr. Boswell Syme is at work on the British Ferns, for an additional volume of "English Botany." A supplement is also in preparation, to include the additions to the Phanerogamic flora of Britain, which have been made during and since the publication of the eleven volumes of the book.

— WALNUT trees sometimes attain prodigious size and great age. An Italian architect mentions having seen at St. Nicholas, in Lorraine, a single plank of the wood of the Walnut 25 feet wide, upon which the Emperor, Frederick III., had given a sumptuous banquet. In the Baidar Valley, near Balaklava, in the Crimea, stands a Walnut tree at least 1,000 years old. It yields annually from 80,000 to 100,000 nuts, and belongs to five Tartar families, who share its produce equally.

— At a recent meeting of the Linnean Society, Mr. D. Hanbury exhibited dried specimens of a Rose raised from seed received direct from the country where the attar of Roses is produced, as the species from which this perfume is obtained. Mr. Baker pronounced it to be *Rosa gallica* var. *dampascena*, the monthly Rose, belonging to the *Centifolia* group, thus confirming previous conjectures on this point. It appears, however, that several varieties are cultivated for this purpose.

— A PRETTY Grape Hyacinth (*Botryanthus palleus*) is now in flower in the York Nurseries; its flowers are pale blue, and the spike somewhat lax, compared with that of *Botryanthus paradoxus*, which is growing beside it, and which is a winter-blooming kind. The spike of *B. paradoxus* is said to be short and thick, the flowers being densely packed, and of a dark rich blue. It may be added that these two Grape Hyacinths keep green all through the winter months, a circumstance which gives them a cheerful appearance.

— THE volume of the *Botanical Magazine*, just completed, is, we observe, dedicated to Mr. Maw, of Benthall Hall, Broseley, as a tribute to the value of his exertions in introducing hardy herbaceous plants into English gardens. "No one," says Dr. Hooker, "of late years, or perhaps ever, has collected with his own hands so many of these for transmission to England, cultivated them with more success, or distributed them with more liberality—as the pages of this work to some small extent testify." No one better deserves such a compliment, a fact to which our own pages also bear witness.

— IN an able article in the current number of the *Fortnightly Review*, Professor Clifford defines science as "organised common sense." We commend the fact to those who, presuming on technical acquirements, divide humanity into two great groups—scientific and not scientific. We need not add in which group they place themselves. Another writer, in the *Pall Mall Gazette* of the 1st December, says, "I expressly use the word 'scientific' as equivalent to 'reasonable, intelligible, and consistent.' But if the use of the word science should turn out to be so liable to misapprehension as some appear to consider it, and if people are found to persist in thinking that one means something opposed to instead of identical with common sense, I should be quite willing, as a matter of temporary convenience, to do without it." It would appear that the true view of the case, long ago clearly enough laid down by thinkers, is becoming more widely spread.

— LARGE tracts of land in the south of France, which have not hitherto repaid cultivation, are now being planted with the kind of Oak trees beneath which Truffles are generally found, and it is expected that each acre of this land, which has of late been sold for as little as £5, will yield a crop of Truffles worth £20 every year. The experiment has already been tried in the department of the Vaucluse, and, according to the *Pall Mall Gazette*, in the course of the last twenty years 150,000 acres which were absolutely unproductive have been planted out, and are now yielding a rich return. The cost of plantation, which is borne by the different communes, does not exceed 20 francs per acre on hilly ground, and though it is rather greater in the lowlands, the crops are proportionately heavier. Acorns only are planted on the hilly ground, but saplings of five or six years' growth, placed in rows about 40 feet apart, are found to answer best in the lowlands. The ground between each row of trees is planted with Vines, which, after five or six years, suffice to repay the cost of the whole plantation and its culture. It is urged that this experiment, applied to the large tracts of land in the south of France

which have been denuded of forests, would have the double advantage of increasing the supply of Truffles, and of replacing the forests, the want of which is very much felt.

— M. VAN HULLE, of Ghent, has lately received seeds of a Water Lily, described as even finer than the *Victoria regia*. The seeds were derived from Paraguay. What the merit of the plant really is has yet to be proved.

— THE present Council of the Royal Horticultural Society is wisely endeavouring to increase its usefulness, and one means by which they hope to do this is to hold meetings during the long winter and spring evenings, at which popular and scientific lectures will be given. A committee has been appointed to carry out this scheme, which, if well conducted, will doubtless prove successful.

— THE current number of the *Florist* contains coloured plates of *Rhododendron Vanban*, a delicate lilac variety, the upper segments of which are blotched with orange-yellow; and *Prince Englebert Plum*, a deep purple variety, covered profusely with bloom. It is a kind that is largely cultivated by Mr. Dancer, and other growers, for market, and this is, perhaps, as good a test of its merit as could be had.

— DR. PFEIFFER'S new "Nomenclator Botanicus" is, according to the *Journal of Botany*, near completion. Its arrangement is alphabetical, and under every name the citations are put in historical order. In separate paragraphs are placed together those authors who agree in opinion as to the position of the particular group, with the addition of the opinion itself. This affords a well-arranged view of the transformations which the system in general, as well as each single group, have experienced in course of time. The historical literary section is the most valuable part of the work of Pfeiffer. The remarks, too, on the etymology of the names are of special value. At present the work comprises only the names known up to the end of 1853, but it is expected that all those which have been since published will be treated in a supplement.

— It will, perhaps, be remembered that we (*Tribune*) gave some few weeks ago, "as news-matter of possible interest," a report of a meeting of the Philadelphia Academy of Natural Sciences, at which a specimen of Wheat, with a head of the *Bromus secalinus* or Chess attached (sent by Mr. Levette, of the Indian Geological Survey), was presented, and spoken of at length by Mr. Thos. Meehan, and examined by the members present, and which, so far as the naked eye could detect, appeared to be a natural outgrowth. In order that there might be no mistake, however, Mr. Meehan moved that the specimen be handed over to the microscopical section of the Academy for dissection, which was done. The Microscopical Committee have now reported, and it appears that the Chess was neatly inserted into the Wheat stalk, and held there by a substance "which the committee believe to be gum tragacanth."

— THE December number of the *Botanical Magazine* contains coloured figures of the following plants:—*Rheum officinale*, one of the most effective of all the species, and interesting as affording the medicinal rhubarb of commerce. It is also figured and described in THE GARDEN, Vol. V., p. 439. It is a native of Tibet and Western China.—*Episcia fulgida*, a brilliant scarlet-flowered Gesneriad, with oblong netted hairy foliage. It is a native of New Granada.—*Boucaersia marocana*, a plant resembling one of the columnar *Euphorbias* in habit, but nearly related to the *Stapelias*. It has glaucous quadrangular fleshy stems, and rich brown-coloured flowers, each as large as a sixpence, marked towards the centre with concentric yellow lines.—*Oncidium zebrinum*, a beautiful and distinct species from Venezuela. It flowered in Sir Wm. Marriott's garden at Down House, Blandford, the branched panicle being 12 feet in length.—*Fuchsia procumbens*, a gracefully drooping species from New Zealand, bearing erect yellow and crimson flowers, the anthers of which are blue.

— GEIGER, in his "Peep at Mexico," thus describes the vegetation near Colima:—"The trees are not large, but are so interwoven as to form impassable barriers, even apart from the bushes and shrubs that spring from every spot of vacant ground. Hundreds of creepers cling to every trunk, and twine round every branch, connecting by a thousand wiry threads, thickets, shrubs, and Cacti—a massive bulwark of profuse vegetation, through which the axe alone can hew a way. The huge *Organo* Cactus, with its tree-like stem, often 2 feet in diameter, and 10 to 15 feet high, sends up its stiff straight branches to a height of 30 or 40 feet from the ground, whilst the smaller species mingle in thousands with the shrubs and bushes nearer the earth. Wherever the creepers may have neglected trunk or bough, prolific parasites, gay alike with taper leaf and gorgeous blossom, hasten to perform their part in this fairy work of Nature. The flowers have little scent, but their profusion of white, yellow, and red, blended with the countless shades of green, charm the eye with tints as various as they are magnificent."

THE INDOOR GARDEN.

PYRAMIDAL COCKSCOMBS.

(*CELOSIA PYRAMIDALIS*.)

Few plants are more useful than these either for conservatory decoration or in the form of cut sprays, and for autumn and winter indoor decoration they deserve more general culture than they have hitherto received. Seeds of them should be sown in February, and, for succession, again in March or April. Treated like Balsams, Cockscombs, and similar tender annuals, they succeed admirably when grown in frames or pits. Like ordinary Cockscombs, they are liable to be attacked by thrips, and especially by red spider. To obviate such attacks, therefore, the seedling plants should be potted off into a rich compost consisting of sandy loam and well rotted hot-bed manure or leaf mould. A genial atmosphere should be maintained throughout all stages of growth, and the plants should be syringed during both morning and afternoon in fine weather. Where fine specimens are required a little bottom-heat should be given them, and where dung and leaves are used in order to obtain such warmth, the genial moisture arising therefrom does much towards keeping all insect pests in check. Shift the plants into larger pots as required, using 12-inch ones for the largest plants. A cool span-roofed greenhouse is the best position for them when too large for pits or frames, and, as the pots become filled with roots, give copious waterings with liquid manure. Like the *Chrysanthemum*, when allowed to get dry at the root loss of foliage is sure to be the inevitable result. Well-grown plants of this class of Cockscombs are often as much as 5 feet in height, and nearly as much in diameter—literally masses of rosy-lilac, purple, yellow, or crimson plumes, which, in some strains, droop gracefully, as shown in our engraving prepared from a photograph of a specimen of this kind of Cockscomb, grown by Mr. Frisby, gardener, at Blankney, the seat of H. Chaplin, Esq. Some varieties are more erect in growth than that here represented; but we like the drooping forms best, inasmuch as they are more bushy and make the finest shaped plants. Well-grown specimens of these Cockscombs are invaluable for grouping along with *Chrysanthemums* and other winter flowering plants, to which they add an agreeable variety; and cut sprays of them, seen under artificial light, have an exceedingly brilliant effect. Mr. Yates, of Sale, who uses such plants largely for decorative purposes, recently sent us some remarkably well-coloured plumes of the crimson kinds, and we also saw some fine compact plants of these *Celosias* lately in Lord Lonsborough's garden at Norbiton. Mr. Denning, the gardener there, classes them amongst the most useful and effective of all bright-coloured winter-flowering plants.

A Pyramidal Cockscomb.

B.

EPIPHYLLUMS FOR WINTER DECORATION.

THE forms which *Epiphyllums* can be made to assume are various—dwarfs on their own roots, standards, pyramids, umbrella-shaped, and rafter plants. When grown as dwarfs on their own roots they are well adapted for hanging-baskets. Grafting at once raises them to a higher level, and allows the flowers to display their

peculiar beauty to the best advantage. The ease with which they may be made to unite with any of the *Cactus* species is also in favour of grafting. *Cereus speciosissimus* forms an excellent stock on which to graft *Epiphyllums*, as it is of strong growth and long duration, and is well adapted for carrying the weight of the *Epiphyllum*. Grafting is a simple matter—all that is required being a good sharp knife and some pieces of the *Epiphyllum*. If for a pyramid, begin at the bottom of the stock by making a cut half through it, into which insert a piece of the *Epiphyllum* cut at the end into the form of a wedge; then bind the whole together with a piece of matting, to keep the scion in its place. Work in this manner round the stock, using smaller and shorter pieces at every upward stage till the top is reached, on which a piece should be inserted. When required in the form of umbrellas, the top of the stock should be cut square and a piece cut out of it in the form of a wedge, into which insert two pieces of *Epiphyllum*. In a growing humid atmosphere and shaded from the sun, such scions will unite in a very short time. As soon as they have got established they should be placed in a stove to make their growth, after which remove them to a cooler and

drier temperature to harden, and finally expose them to the full blaze of the sun to induce them to set their flower buds. They will begin to bloom in November, and by removing a few at a time into a warmer house, the blooming season may be prolonged till the month of February. During the growing season they will require a plentiful supply of water, and, while coming into flower, one or two waterings with liquid-manure will be of advantage to them; but they should now be watered more sparingly than they have been, for if the soil gets over-wet or sour, the flowers will last only a very short time. During the dormant months few waterings will be necessary. The best soil for *Epiphyllums* is a good fibry loam, some lime-rubbish, a few half-inch bones, and a little cow-dung. The pots in which they are grown should be well drained, an essential point. Do not over-pot, as they will flower best when they get pot-bound. If a plant trained in the form of a pyramid or umbrella be placed in the centre of a vase surrounded with some dwarf plants of *Bouvardia*, and a few plants of the variegated *Panicum* to hang as a fringe, it forms an effective ornament for the drawing-room; and what adds to its value is, it will continue in perfection for several weeks. Anyone who has seen the beauty of this plant when grown in the form of a pyramid or umbrella, has some idea what it is like when used as "a creeper." For this purpose the *Pereskia* forms an excellent stock on which to graft it, on account of the ease with which the *Epiphyllum*

unites with it. This stock is by no means difficult to grow. Cuttings of it may be put in during the spring; and, when rooted, pot them off singly into 3-inch pots and keep them in a stove temperature, where they will grow very fast, and will soon fill their pots with roots. As the plants grow, they must be shifted into larger pots, using a soil composed of fibry loam, some cow-dung, some lime-rubbish, and some ½-inch bones in a somewhat rough state. Give abundant drainage, as the plants when growing will require a liberal supply of water at the root, which must be allowed to percolate freely through the soil. March and April are the best months in which to graft; but this operation can be performed at almost any season. Cover the *Pereskia* from top to bottom, at distances of about 6 inches apart, with pieces of the *Epiphyllum*, which may be kept in their places by being pinned with one of the spines that grow on the stock. Give them the same treatment as recommended for pyramids, and thus managed, when in blossom, nothing can excel the beauty of this plant when trained up the rafters of an intermediate house or warm conservatory.—*The Gardener.*

THE GARDEN IN THE HOUSE.

FLORAL WREATHS AND CROSSES.

Day by day the custom of placing floral offerings on the graves of departed friends and relations, is, I am happy to say, coming more and more into vogue. Some have a dislike to this custom, but for my own part I cannot see with what reason, as, after all, what can be more appropriate for such a purpose than flowers? Such decorations generally consist either of dried or fresh flowers. Of the latter I shall treat fully, but of the former merely remark that it is much better to buy them ready made than to make them, as one never can command such a selection of dried flowers and Grasses as can be obtained ready mounted in the florists' shops in Covent Garden. They can be bought, too, of every size and form, and at a cost to suit the means of every purchaser. Living flowers for the purpose of laying on tombs are mostly mounted in three forms, viz., wreaths, crosses, and flat bouquets. The colours selected should be of delicate hues, as bright and glaring colours would be quite out of place for this purpose. For a young or unmarried person, pure white is generally selected, and for a married or elderly person, violet or mauve is a pretty colour to introduce. The selection of flowers must of course depend on the season of the year. The foundations of crosses are mostly made of flat laths, such as are used by plasterers in the formation of ceilings, or straight hazel rods; that of wreaths, of wire; and for flat bouquets, branches of Yew are most frequently employed. In these different devices a quantity of Wood Moss is used, particularly where they take the form of a wreath or cross, for, as well as preserving the freshness of the flowers, it also forms the foundation or mat of green into which the flowers are worked or bedded, if I may be allowed to make use of the term; and, on account of occupying so prominent a position, only that which is perfectly green and fresh-looking should be employed. All Moss to be used in the construction of crosses should be well washed in water, so as to remove all particles of decayed leaves and chips of sticks which are always to be found through Wood Moss. After it has been passed through the water till quite free from such rubbish, the moisture should be gently squeezed from it, except enough to keep the flowers fresh, without leaving a damp mark where the decoration rests. When this has been done the Moss should be picked over, and all the stems placed in one direction; for, the points of this Moss being of a lighter and prettier tint than the other portions, by placing them in this manner an evenness of colour in the foundation is obtained. The formation of a wreath is very similar, except that to keep the circle perfect requires more practice than the straight lines of a cross. Having some strong wire, the Moss, the flowers, and a reel of fine binding wire ready prepared, the formation, say, of a wreath, may be thus proceeded with. First, make a piece of the strong wire into whatever sized circle is required; then take some of the Moss and bind it with the wire off the reel on to the stouter wire, catching the stems of the Moss about half way down with the former; keep the Moss as even as possible, and make it a perfect bank or ribbon of green of a width in proportion to the size of the circle. Into the Moss, as you go along, the flowers should be worked, the Moss being pressed up close to them, so as to give them moisture, and also to keep them firmly in their places. The most difficult part of the wreath to complete nicely is where the stems of the Moss meet in the finishing of the circle. When it comes to the junction, the Moss must be worked in both ways till the space is filled by one finishing tuft. In a cross the end is the most difficult part, and this must be finished in a similar manner. In flat bouquets, much Moss is not used, at least not in proportion to the amount employed in crosses, &c., all that is required here, being just sufficient to keep the flowers fresh mounted on twigs or stub wires as in a hand bouquet. Most bouquets of this kind are made of an oval or pointed form, the centre being composed of some large-sized flower; Arum blooms are favourites for this purpose. As to the selection of flowers, as I before remarked, they must be in accordance with the season of the year, and I think the best guide I can give for this purpose is to give descriptions of a few decorations I have made myself at different seasons of the year. In November, I once made a wreath of large dimensions, composed of the following flowers—White Camellias, Eucharis, Bouvardias, Roman Hyacinths, Neapolitan Violets, and Ferns of the following varieties, *Adiantum cuneatum*, *A. marinum*, and *A. Trichomanes*. In December I made a cross about 18 inches high, composed of white Camellias and Roman Hyacinths only; also, at the same time, a flat bouquet, in which the following were employed—white Azaleas, Bouvardias, Eucharis, Roman Hyacinths, Heaths, and a large sized Arum bloom, with Fern fronds interspersed through the whole. Late in February, I made a large-sized cross, about 3 feet in length, of white Camellias, Snowdrops, pips of a lavender-coloured Hyacinth, and Fern fronds; and, at the same time, two flat bouquets

of Violets and Primroses. During the summer months such flowers as Lilies, white Rose buds, Lily of the Valley, &c., could be substituted for the above, which I have merely enumerated on account of having used them myself, and because their names indicate the style of flowers which should be employed when obtainable. Box and similar shrubs are much used in the construction of wreaths and crosses sold by the florists, on account, I suppose, of their being more quickly made with such materials; but I myself much prefer the fresh green of the Wood Moss. In the same manner as I have described, can be fashioned floral ornaments, such as are so much used at Christmas, Easter, and Whitsuntide in our churches. The large wreath which I have described would be well adapted for the decoration of a font, or, perhaps, it would be more suitable for that purpose if it were made of white flowers; however, the plan and mode of manufacture would be just the same in either case. The cross and flat bouquet would do well also for the decoration of an altar. In the construction of crosses or wreaths, too many large flowers, such as Camellias, should be avoided, as they tend to give the decoration a flat and heavy look, which should be carefully avoided. It is the fact of too many flowers of this kind being employed that makes these styles of arrangement, when exhibited in the florists' windows, appear out of keeping with their hand or button-hole bouquets, as regards lightness, and there is no reason why this should be so. Lightness is the great perfection of art in all floral arrangement, and why should it not be carried out in this branch as in any other, save that the more Camellias are employed, the more is charged for the ornament? I have seen wreaths exhibited in Covent Garden made solely of white Camellias, packed as close as they could be; the effect was heavy and bad, and, for about half the cost a much more effective arrangement could be made with flowers of a lighter growth, only a few Camellias being employed in its construction.

A. HASSARD.

HANGING BASKETS.

WHAT looks better than pretty hanging baskets tastefully filled with plants? and yet, how seldom are they to be met with! Baskets of living plants may easily be had in perfection; select such kinds as will stand in rooms. As regards the baskets themselves, I like to see the wire-work painted dark green. Some paint it with bright colours, which quite spoils the effect of the flowers, which should be gay enough, as regards colour, without any addition in the way of paint. Inside the wire-work put a thick layer of green Moss, so as to prevent the soil from dropping through, over this put some broken crocks, and then fill up with whatever compost is best suited to the requirements of the plants with which the baskets are to be filled. For summer decoration there are numberless plants that can be grown in baskets; but, for winter blooming, nothing is better, or looks more showy, than Rollisson's Unique Geranium or Scarlet Tropæolum, both of which will continue in flower all through the winter, and droop down gracefully all round the basket. A basket, indeed, never looks well unless it is furnished with some drooping plant round the edge, as, for instance, with the variegated Ivy-leaved Pelargonium, called L'Élégante; while, in the centre, should be a nicely-grown plant of Fuchsia Mrs. Marshall. Pretty baskets may also be made of silver variegated Geranium Lady Plymouth and bright blue Lobelia, or of blue Convolvulus, with Christine Geranium in the centre; in fact, any flower that suits, and is put in with good taste, will look well. For large baskets, suited for lobbies, mixed foliage plants, such as variegated Sedums, Echeverias, Fesines, and Centaureas, have an effective appearance. A window box made of wood, and lined with zinc, suspended by four cords or wires, on which can be trained creepers, also makes a pretty room ornament. The great point as regards creeping plants in baskets or boxes fresh and in good health is to give them plenty of water during the growing season, but more sparingly in winter, and to keep the leaves clean. If baskets are hung high there should be some means of lowering them, as it is troublesome getting up to them every morning with steps. If the baskets are small, the best way is to carry them away and water them outside; but in the case of large baskets this cannot be done, so a tea tray or something of the kind should be placed under them to catch the drip.

H. A.

Rustic Picture Frames.—Pretty frames may be made with nuts and cones. I lately saw some made of Beech-nut shells, fully open, along with others not so far advanced, Acorns, Hazel nuts, and numerous small cones of different sorts, the whole forming a pretty and effective frame, which may be either square, oval, circular, or hexagonal. A piece of strong card-board is brushed over with glue, in which the nuts are set on a ground-work of dried Lichens. The larger cones are generally placed singly, but the smaller nuts are mixed and grouped together. When finished, the cones and other parts receive a slight coating of varnish. Where plenty of cones and nuts can be had, very pleasing combinations might be made in this way.—J. MUIR.

THE FLOWER GARDEN.

THE JALAP PLANT.

(EXOGONIUM PURGA.)

Of all autumn-flowering hardy plants, there is, perhaps, none more beautiful than the Jalap (*Exogonium Purga*). Of its complete hardiness there can be little doubt. It has lived at Bitton without any protection for four years, and each year it has flowered beautifully. We have also heard of its doing well at Drayton Beauchamp, Kew, and Fulham. We believe it has also lived out of doors, and flowered, in the Edinburgh Botanic Gardens. Mr. Ellacombe grows it in a sheltered corner, and gives it a tall wire cage to grow up, with a spreading top. It does not flower in the lower parts; but the entire top, and the pendent shoots, become a mass of most lovely blossoms. At Bitton, if not checked by late spring frosts, it comes into blossom early in September, and continues to flower till cut down by frost. Mr. Ellacombe states that, if he were to plant another, he should place it under a south wall, near a Peach or Apricot tree, and let it wind its way through the branches.

Leaves, flowers, fruit, root, &c., of the Jalap plant.

With a very little training, it would do no injury to the tree; and, in such a situation, it would probably flower earlier, and perfect its seeds. As regards its history, it gets its name of Jalap from its native habitat, Xalapa, in Mexico. It is the true jalap of commerce; by which is not meant that it alone produces genuine jalap, but that it is the plant that gives the name to the medicine. The best jalap is made from the *Exogonium*; but good jalap may also be got from many other species of the *Convolvaceæ*—even from our British species. "*Convolvulus arvensis*, *Solanella*, *macrocarpus*, and probably many others, may likewise be used with nearly equal advantage," says Dr. Lindley. The habit of the plant is well given in the *Botanical Register*, v. 33; but the colour is not bright enough. It is also figured in the *Botanical Magazine*, v. 73. Can any one say if *Convolvulus* (*Batatas*) *Jalapa* is in cultivation, and if it has been found to be hardy? *E. Purga* has, as will be seen, roundish tubers of variable size, those of mature growth being about as large as an Orange, and of a dark colour. These, as we have said, are the true Jalap tubers.

MUILENBECKIA COMPLEXA.

This is a New Zealand plant sometimes met with in greenhouse culture under the name of *Polygonum complexum*. That it is perfectly hardy, a twelve years' culture out of doors will, I think, bear ample testimony. That it possesses qualities such as ought to commend it for general culture, whether as a wall-creeper or as a charming neutral-tinted zone in a flower-bed, any person who has seen it will at once admit. In this double capacity it has been for several years one of the chief decorative features of the front of my house, and is admired by every one; and when I say that the popular impression is that it is a bank of Maiden-hair Fern, I think I have said enough to justify my wish to see it introduced into more general cultivation. In the first place it is, as I have said, perfectly hardy, and in the second it possesses all the unobtrusive simple beauty of the small-leaved *Adiantums*—for the popular comparison is by no means inapt—why then, it may be asked, has its cultivation not become more general? To this I may reply, that its perfect growth and full development are not attained with that rapidity which must be looked upon as characteristic of the present age in things general, and no less in things horticultural, but more especially is it characteristic of that section of horticulture to which flower gardening belongs. I have given scores of plants away to my gardening friends, but have never yet seen them utilised to even a limited extent. Let me endeavour to describe the process by which the results I have stated in my opening remarks have been attained.

About eleven or twelve years ago, from a plant growing and rambling and scrambling freely over a bit of rockery, I went to work and struck a score or two of cuttings, under the impression that the plant possessed a value beyond what was indicated in this, its almost natural condition. These, after a year's growth in pots, I planted out in a semicircle, pegging down the longer shoots, and, during the season, occasionally clipping back any stray shoots. Certainly, for the first couple of years, it did not look very promising; but, in the third, it had acquired sufficient compactness to form a continuous line of leaf tracery, all the more beautiful on account of its extremely slender dark brown stems, and also the peculiar olive-brown tint of the leaves themselves. This semi-circle, or zone, has since that, year by year, increased in density, and forms a mass about 6 inches high and 15 inches or so in width, requiring no attention beyond clipping with a pair of shears two or three times during the summer. At either end, next the wall, its twining branches have been allowed to grow, and they will soon have surrounded the lower windows with a sort of leafy framework of exquisite beauty. Some of my floral friends may say, "But what are the flowers like?" To this inquiry I can give no satisfactory reply. Though I have known the plant for over twenty-five years, I have never seen it bloom. This I am the more anxious to see from the fact that it is said to have a baccate, or berry-like, fruit; and in that fact chiefly rests its claim to the special generic title of *Muhlenbeckia*—a name by no means so euphonious as that of the old classical *Polygonum*. Therefore, on the beauty and singularity of its tiny round leaves and its twiggly dark stems alone it rests its claim for popular favour. But it possesses a value beyond even these—namely, as a pillar plant; whether secluded in a sort of recess in the ordinary shrubbery, backed up by the light green foliage of Laurels, &c., with which it forms a striking contrast, or standing alone on the Grass, it is in either case an object of the greatest beauty. The way in which this, its third attribute, was elicited, it may interest some of your readers to know. I will therefore briefly describe it as follows:—At the same time as I planted out my experimental semi-circle, I sent a plant to my father at Dublin, merely stating that I contemplated making something of it, and asking him to do the same. Singularly enough, while my ideas altogether ran in the horizontal, his assumed the perpendicular, and whereas I pegged mine down, as before described, he trained his up to a stake. A few years after, on paying a visit to the paternal domicile, at the Garden Farm, I was delighted to find his plant presenting the very *beau idéal* of a vegetable fountain; it was then about 6 feet high, and appeared like a gushing stream of leaves, rising to the height described, and falling, as it were, down the long pendent

branches, whose ends swept the surface of the ground. In a letter from my father the other day he describes it as one of the most effective plants he has; it is now 12 feet high, attached to a stout pole, its means of support being completely hidden amid its dense mass of spray-like branchlets, and on the ground a mass of growth some 6 or 8 feet in diameter, of irregular outline, that appears to me, from his description, to realise the fountain picture I have already endeavoured to describe, with its basin of spray-tossed foliage beneath. Accompanying the description, he sends a rough sketch of the plant, which, from what I have already seen, I can easily understand, but, to do it justice a good photograph, supplemented by the best skill of a good engraver, would be required. Possibly, I may on some future occasion obtain the former, and, however difficult it may be, I have no doubt you would be able to supply the latter. Nor does its value cease here, as it forms an exquisite suspended plant, admirably adapted either for a conservatory or window. Under these conditions its wire-like stems, and rounded leaves are exhibited to the utmost advantage, and in a hanging basket its lack of brilliant blossom may be always supplemented by associating it with other plants to which *Flora* has evinced a greater mead of generosity in the distribution of her favours. The *Muhlenbeckia* is by no means difficult to propagate, it strikes freely in a cold frame, if the cuttings are put in in September, the only point to be observed is that in selecting the cuttings, they should be taken from the thicker shoots that are generally sent up from the ground in the form of snekers, not from the twiggy shoots; the former strike freely and form snug little plants the first season; the latter, if they do strike, will be at least two years before they form well-established plants.

While writing the above I am reminded of another hardy New Zealand plant, which was alluded to at page 124 under the name of the golden-leaved *Diplopappus*. A good many years ago I gave it that provisional name when sending it out to my numerous correspondents; and, seeing that I was unwittingly guilty of giving it a misnomer, I avail myself of this opportunity to correct it. When it bloomed with me, some years ago (growing freely as a hardy shrub, which it has done for the last fourteen years), I found that it was more nearly related to the old genus *Ozothamnus*. I sent it to Dr. Hooker, and he pronounced it to be *Cassinia Vanvillarsii*, a genus closely related to the former. It produces numerous small whitish flowers in compact clusters; though pretty in their way, they are not sufficiently showy to recommend the plant for general culture; but its golden coat, which suffuses the back of the leaves, and still more densely the entire young stems, will always make it an object of interest. By-the-way, my original name was *Chrysochlada*, not *Chrysophylla*, the former meaning literally golden coated, the latter only golden leaved. In adapting it to general purposes as a bedding plant, it has not realised my expectations; but, as a shrub, it is well worth growing for its own merits, as also from the interest that attaches to it as one of our few hardy New Zealand plants.

Hull Botanic Gardens.

JAS. C. NIVEN.

BULB BEDS IN SEVERE FROSTS.

SEVERAL years ago, when my enthusiasm in horticultural affairs frequently got the better of discretion, I made some very expensive blunders which I never like to talk about, unless for the purpose of keeping somebody else from falling into the same ditch. Once upon a time Mrs. "Ruralist" suggested that large beds of early, spring-flowering bulbs would be a great addition to our garden; and, as I fully agreed with her in this matter, arrangements were made to carry out the suggestion. In the woods about a mile distant, I found a spot where charcoal had been made several years before, and the debris of fine coal ashes and black soil was quite plentiful. These materials are supposed to be excellent for bulbous plants of all kinds, and of course I hastened to secure them of the owner of the land. Twenty-five loads were brought, and bulb beds made according to rule, and upon scientific principles. When ready, I made my selections of Hyacinths, Tulips, Crocus, Narcissus, and other suitable kinds that would make a good show. I confess to have secretly thought that I would surprise Mrs. "Ruralist," not with the quantity but with the quality and beauty of the varieties; consequently only the very choice named sorts were

purchased. The bulbs were planted at the proper season, and, I think, in a proper manner. As some of them were considered not perfectly hardy, I made arrangements to give protection in winter. Besides, did not and do not the garden calendars recommend this, even with the most hardy kinds? Of course I was well aware that mice would eat these bulbs if they could get at them; but, when buried several inches deep in the ground, danger from this source appeared to me out of the question. When the ground began to freeze the bed was covered 4 or 5 inches deep with coarse hay, and no further attention paid to it until spring, then the covering was removed. We then discovered that the ground moles, finding a sheltered spot, had congregated there and, probably assisted by field mice, which follow in their burrows, the two together had made a clean sweep of my choice bulbs. About a dozen Hyacinths only, on the outer edge of the bed, where the ground remained frozen to a considerable depth, were left of the entire collection. Had I kept the hay off the bed a week or two the ground might have become so hard frozen that the moles and mice could not have made an entrance; still there are always more or less flaws in winter of which such vermin will take advantage. If there are no mice or moles about a place, then protection with coarse litter will answer; otherwise there is always more or less danger in applying anything to beds containing bulbs which will prevent freezing, because vermin are pretty certain to congregate in such favourable locations. I frequently hear of the loss of Lilies, Hyacinths, and other hardy bulbs, the purchasers attributing their failures to unhealthy plants; and while this may be the true cause in some instances, still I am inclined to think that moles and mice get more than they are accused of taking.—*Moore's Rural.*

Wake-Robins (Trilliums).—The genus *Trillium* is a purely American one, with the exception of one species which is found in Japan. About ten species belong to the genus, all of which are interesting, and some sufficiently showy to claim a place among choice border flowers. The *Trilliums* would not at first sight be placed in the Lily family, as their general appearance is so unlike that of the Lily; yet the structure of the flowers is such that recent botanists have thus classed them. The genus gets its name from the Latin for triple, the parts of the plant being in threes; we have three leaves upon the stem, three parts to each calyx and corolla, twice three stamens, and the parts of the pistil in threes. They all have a tuber-like root stock from which arise a few simple stems about a foot high, each bearing three broad leaves, and above these the flower, which is either elevated above the leaves, upon a stem, or sessile close among them, as in the case of *T. sessile*, lately figured in the *Agriculturist*. The flower of this species is a dark purple or maroon colour; but the great beauty of the plant lies in the leaves, which are finely variegated or marbled with a very pale and a dark green, and, when perfect, equalling in richness some of the choicest of greenhouse foliage plants. This species is found from Pennsylvania and Wisconsin, southward; and in South Carolina and Florida there is a closely-allied species, *T. discolor*, which has still more strongly-marked leaves, but otherwise nearly related to this one. The *Trilliums* will grow in any good garden soil that will not become too dry in summer; and, when they become well established, a process requiring a year or two, they will take care of themselves, and unfold their flowers every spring. The large-flowered *Trillium* (*T. grandiflorum*) is a remarkably handsome plant, which has received the name of the white Wood Lily. It should be grown in moist, shady, sheltered spots, by the sides of wood walks, in moist shady hollows of the rock-garden, or in the hardy Fernery along with Royal Ferns, and similar moisture-loving plants. In such situations its pure white blossoms, produced freely in spring, are strikingly effective. *T. cernuum* is another interesting kind; which flowers later in spring than *T. grandiflorum*. It succeeds well among shrubs in moist peat borders, or it might be planted in moist spots in the hardy Fernery or rock garden.

Spiræa palmata.—Some of our readers will call to mind a plant bearing this name brought out in England with a flourish of trumpets similar to that which attended the introduction of *Primula japonica*. It was sold at a high price then, and is even now priced in the catalogues at from 3s. 6d. to 5s. sterling. Yet it is by no means a new plant, having been first introduced into England from Japan in 1823, and grown in many collections of herbaceous plants of that period. It is a curious instance of the result of neglecting the cultivation of hardy perennials for that of bedding-out plants, when an old inhabitant of our gardens can be brought forward and sold at ten times its original price. The specific name *palmata* has been applied to no fewer than three different plants of the *Spiræa* family. The first, of which we have just spoken, is described in Thunberg's "*Flora Japonica*," and is a native of Japan. There

appears to be two varieties of it, as he speaks of it as having white or red flowers. The second is *Spiraea digitata*, a native of Eastern Siberia, named *S. palmata* by Pallas, the Russian botanist. The third is *Spiraea lobata*, a native of this country, named by Linnaeus *S. palmata*.—*American Garden*.

THE MALE HARDY PALM.

(*CHAMEROPS EXCELSA*.)

THE interest attached to this Palm as an ornamental plant, and particularly the remarkable difference existing between male and female plants of it, have induced us to present our readers with the accompanying sketch of the male variety. The male kind is known by its large thick trunk which, near the ground, branches out into strong vigorous boughs, thickly covered with spiky foliage of a deep yellow colour; these spikelets at first grow out straight from the branches and then incline sharply downwards. It bears innumerable little flowers, growing closely together, of a beautiful deep orange colour tipped with yellow. The female is comparatively small, with much thinner branches, the greenish-yellow leaves of which grow straighter than those of the male sort, describing no curve or angle till much further from the stem. Its numerous small flowers, of a pale yellow hue, also grow at greater intervals apart. It blooms

from April to May, and the seeds ripen from February until April the following season, thus requiring an entire year for complete fructification. As regards display, the preference must be given to the male trees, which may well be pronounced exceedingly ornamental. It is a moot point whether the males or females are most numerous. Certain circumstances would indicate that the males are. For instance, at Bordeaux, M. Duriende Maisonneuve has only one plant of the female variety in his shrubberies, whilst quantities of males grow there. M. Thuret, of Antibes, also informs us that all the plants (four in number) which have flowered with him are males; but at the Paris Muséum the reverse appears to be the case, since out of five plants which have recently bloomed there four are females.—*Revue Horticole*.

The Male Hardy Palm.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

True Creepers.—I find the word "creeper" in *THE GARDEN*, and other horticultural papers, often erroneously applied by correspondents to all climbing plants. Now I hold that true creepers are only those which adhere to, or creep up a wall by means of rootlets or tendrils, and without the assistance of nails or trellis. Of these, I believe, there are but three hardy species, and shall be glad of correction if I am wrong. These three are—*Bignonia radicans*, Ivy, and Virginian Creeper and their respective varieties. *Ficus repens*, another true creeper, has proved itself hardy in some places, but can scarcely be quoted as such generally.—T.

Evergreens for Beds in Winter: A. H. Aucubas of many sorts, green and variegated Box, common and Portugal Laurels, green and variegated Hollies, *Aralia Sieboldii*, dwarf Junipers of sorts, *Ligustrum coriaceum*, *Raphiolepis ovata*, *Viburnum acerifolium*, *Osmanthus* (green variegated), *Biota elegantissima*, *Daphne Triniana*, Tree Ivies of sorts, *Thuja dolabrata*, *Thuja dumosa*, *Taxus japonica*, *Erica herbacea carnea*, *Berberis Aquifolium*, *Andromeda*, *Pernettya* (in sheltered situations), variegated *Eunomyia*, *Laurustinus*, *Skinmias*, *Retinosporas*, common Yew, *Eunymus radiatus variegata*, *Taxus elegantissima*, *Thuja borealis*, *Thuja aurea*, *Juniperus Sabina variegata*, and *Cupressus Lawsoniana* (Waterer's green form of it). Any dwarf Conifer or handsome evergreen that is compact may be used. Many Japanese plants are among the best for this purpose. They should be procured early in autumn, and be placed in pots sufficiently large to hold the roots without cramping; plunge them in the beds deeply enough to cover the pots.

THE FRUIT GARDEN.

UNHEATED STRUCTURES FOR THE CULTURE OF THE VINE.

Of these the only glass structure to which allusion may here be made is the ground Vinery. This is simply a span-roofed frame, with moveable ends, from 2 to 6 feet wide, and is made in lengths of from 6 to 12 feet. It is laid upon the ground, with its ends running north and south, and the Vines are trained under the ridge. Being portable, it is suited to the wants of the small amateur who can grow a few Grapes in it during the summer, and store plants, or grow salads in it in the winter and spring months. For Grape growing upon a moderately large scale it is, however, not to be recommended, as it is obvious that its adoption beyond certain limits would be attended with more expense and less satisfactory results than a properly constructed Vinery of equal capacity.

Grape Walls.

A Grape wall to be of any service should be 10 or 12 feet high, and flued, so that it may be heated when needful; this will be an undoubted advantage, and hardly more expensive in construction than if no means of warming were secured.

A wooden board 14 inches wide, or a glass coping at the top, throws the rain off and, in a great measure, affords protection from the frost. The Vines are trained to wires placed 6 inches apart, and 4 or 5 inches from the wall.

Vine Borders.

Under this heading I propose to treat of the heating, formation, and composition of the border, bottom-heat, and fermenting materials. The propriety of affording the roots of the Vine a temperature corresponding with that of the branches has always been recognised, and the

practice of applying heat artificially to the roots by the aid of fermenting materials probably began with the culture of the Vine under glass, or soon after, and is still the plan most generally and necessarily adopted in the production of early Grapes, and in skilled hands has always been productive of good and lasting results. Whether the border is inside or outside, a gentle hot-bed, by pushing the roots into early and healthy action, and keeping them near the surface where they are more under control, never fails to produce good effects; and the plan has often been fallen back upon when all other means have failed to get up vigour in feeble and exhausted Vines. Indeed, I am aware of cases where the hot-bed system has been resorted to again in a systematic way after an elaborate system of heating the borders by means of hot-water pipes had been tried, and failed through mismanagement or some other cause. The materials for the hot-bed are litter and leaves, which are generally plentiful about most gardens. Stable litter alone is too quick and violent in its action, but mixed with leaves, in greater or less proportions, almost any degree of heat may be steadily maintained for any length of time, provided the bed is turned occasionally and fresh materials added as required. When the hot-bed is the only means available for applying heat to the roots, the

border should be covered in autumn with about a foot of litter and leaves, which will be sufficient to keep the soil at a temperature of 50°, or thereabouts, more by preventing the natural heat of the soil from escaping than by any positive action which a layer that depth exercises. As the Vines progress, and the temperature of the Vinery is raised, so must be the temperature of the border by adding more litter and leaves, and turning the whole over and mixing it thoroughly about once in three weeks; and this practice must be continued until the maximum temperature is reached, when the Grapes are approaching maturity. After this, the temperature may be allowed to decline gradually, until the Vines are going to rest, when the hot-bed should be reduced to a mulching only. As a rule it is seldom necessary to keep the temperature of the border above 75° or 80°, even in the case of Muscats; and I find, by constant experience, that a fermenting bed of an average depth of 18 inches or 2 feet is sufficient to keep the soil of the border at a temperature of 80° 18 inches below the surface. As an instance of the effects of hot linings annually applied, I may state that in 1865 I had to deal with a house of old Vines about sixty years of age, which were in a very feeble condition; but it being necessary to keep them on, and make the most of them for a few years longer, I began by applying hot linings to the border in November, keeping them up till July the following year, the Grapes being wanted in June; and this practice I continued for six years. The effect, after the first and second years' application, was to bring a host of roots to the surface of the border (there were none before), and to restore vigour to the debilitated Vines, from which I cut Grapes of excellent quality annually up till 1872 for my employer's table during the London season. In June, 1871, I exhibited six bunches of Black Hamburgs from these Vines at the Royal Horticultural Society's show at Nottingham, which were reported upon by the horticultural press at the time as "capital Black Hamburgs, cut from Vines more than fifty years old, which are restricted to one rafter, and pruned to the best bud." The rods were only 14 feet in length, and were cropped at the rate of 20 lb. to the rod; and the last year I took nearly 30 lb. off one Vine. When it became necessary to remove this old Vinery in its turn, I was undecided for a while whether to retain the old Vines or plant new ones, so well had they behaved, and so vigorous were they. Their restoration was entirely due to the annual application of hot linings to the border, as in no other way were the roots meddled with. No doubt many instances of this kind could be reported. The hot-bed system has been characterised as cumbersome, untidy and expensive. It is cumbersome comparatively, untidy it need not be, and as for the expense, it will be found—when we calculate the expense of heating a Vine border with hot water pipes, the cost of fuel, and the extra care and attention required in the way of firing and watering, &c., not to mention the fact that over-heated borders have to be protected on the surface somehow—that the hot-bed system is the cheapest in the end. Early Vinery borders are now generally made inside, however, and the hot-bed is not so essential in such cases; but in the majority of gardens no other means of applying heat to the border are available, and it would be unwise to ignore the practice here.

Heating the Border by Hot-water Pipes.

No subject connected with Grape culture has been productive of more controversy than this. Some good gardeners advocate this system of heating, while many others, who have had ample opportunities of testing the system practically, condemn it, as being not only dangerous and unnecessary, but even disastrous in its results. I have now before me a letter from an eminent gardener, the superintendent of a noted establishment, where all the early Vinery borders are heated by hot-water pipes in a most complete manner, in which he reports his past and present experience of the system during the last fifteen or twenty years as follows:—"In reply to your inquiries about the working of the bottom-heat in the early Vineries here, I have to state that I find it of little or no advantage, but the source of considerable danger in our naturally dry and warm soil, if it is not closely watched, so that I have given over using it, except for a few days at starting, after which the fire is put out, and not lighted again till the

following season. I always water with warm water, which I believe is quite as effective and far safer than bottom-heat. In cold or wet localities, or soils, a well-arranged system of bottom-heat might be of more service than it is here for early forcing; still it must be used with the greatest caution, even in such places, for a day's neglect by the man in charge of it would pretty well settle the crop for that year. The system was tried in almost all forms at T. when I was there, between 1850 and 1860, and no place wanted it more, considering the soil and climate; but it never worked satisfactorily, and was the cause of no end of 'rows' and extraordinary crops of red spider instead of Grapes. It has long been discontinued there now, and Mr. — only covers his outside borders with 18 inches of litter and leaves, and wooden shutters to throw off the rain, and has better crops of Grapes than was ever produced there with bottom-heat. This is my experience of the system, but I know of no instance in which it could be said to have worked satisfactorily; in fact, I cannot point to a place where it has paid for the cost or fixing, therefore I am no advocate of the system in any form in which I have yet seen it applied." The experience here related tallies exactly with my own here and elsewhere, and with that of others of whom I have made inquiries concerning the matter. Still, though the system has been hitherto disappointing in its results (and it is doubtful if ever it will bear being measured by a debtor and creditor account), it finds favour with some good Grape growers, who continue to advocate it, so that we may yet see it applied successfully. It is not a question of bottom-heat, the advantages of which are undisputed, but how to apply it with safety on the hot-water principle. Vegetation flourishes around hot springs and above subterraneous fires, but in such instances the source of heat is so deep as not to be felt injuriously upon the surface of the ground; were it otherwise, the effects upon vegetation would be similar to those produced by hot-water pipes when placed in proximity to the roots of a plant, but place the pipes deep enough, and we get quit of all risk and danger. In fig. 1, I have shown how this may be accomplished. The pipes are laid in narrow chambers 15 inches below the surface of the sub-soil and covered over; the border is then formed above, in the usual way, as if there were no pipes there at all. By this plan the sub-soil has to be heated first, and it is, therefore, impossible that any scorching, or bad effect from pipes made too hot, can take place, such as happens when the pipes are so arranged among the rubble or otherwise that the heat at once accumulates among the drainage at the bottom of the border, and must at times be violent and often irregular, according to the care and intelligence of the fireman. The only objections to this plan are, that the stokehole would have to be 15 inches deeper than usual, and the expense of getting up heat would be a trifle more, neither of which are obstacles of any importance. For reasons which any gardener understands, the bottom-heat pipes should be worked by a separate boiler.

Aerated Borders.

This is a simple, safe, and inexpensive plan of warming the border (subject to weather conditions), by means of air drains, which run among the rubble at the bottom of the border, and communicate with the air by means of earthenware pipes placed at the outer edge of the border, and at the back wall inside, and projecting a few inches above the surface, as shown at A B, fig. 7. The air, owing to its greater gravity, descends at A, and, circulating among the drainage, and communicating its heat to the soil in its passage, is sucked out by the rarified atmosphere of the Vinery at B. The drains traverse the border in both directions, intersecting and communicating with each other at right angles every 4 feet; and the tiles, which should be 5 inches in diameter, are laid about 3 inches apart, in order to let the air percolate amongst the drainage, which should fill up the interstices, and cover the tiles over about 4 inches deep. Above all thick sods are laid to prevent the soil of the border from being washed down amongst the drainage, and the aerated chamber is complete. The outside pipes are fitted with plugs, and in working the drains these are taken out whenever the temperature of the external air is above that of the border. When the borders are all inside, as in early Vineries they should be, the aëration system may

be adopted by placing the feed pipes at the coldest part of the house, and drawing the air in by an exhausting chamber placed near the boiler, or at the warmest part of the house and into which all the drains lead. This system may be said to have been inaugurated chiefly by Mr. Fowler, gardener to the Earl of Stair, at Castle Kennedy, whose success as a Grape grower is well known; but, in estimating the results of the system as applied at Castle Kennedy, it must be borne in mind that Mr. Fowler employs fermenting materials in a systematic way as well, applying about 18 inches of litter and leaves to both outside and inside borders, by which means he keeps the roots of the Vines in a vigorous state of activity.

J. S.

(To be continued.)

ON THE CULTIVATION OF VINES IN POTS.

THE cultivation of the Grape Vine has been a study of mine for many years, and, I think, I may say I have met with a fair share of success. Where there is convenience for fruiting Vines in pots I very strongly recommend their growth. Where there is not sufficient convenience to grow the young Vines in their early stages, they can be procured from most nursery establishments. I am of opinion that Vines for fruiting may be bought even cheaper than they can be grown by a gentleman's gardener or an amateur, because it is seldom that sufficient room can be spared for their proper development. Vines in pots, when well grown, are most useful in several ways, not the least interesting of which is the ornamental appearance which they have when placed in vases on the dinner-table. By the following arrangement a beautiful effect may also be produced. Instead of putting the Vines on the table, place them at intervals down each side, concealing the pots under the sides of the table and arranging the tops so as to form an arch over the table from one side to the other, keeping the arches all the same height, and shaping them with hazel rods, to which the Vines are neatly tied; green Moss and Vine leaves may be woven round to hide any bare stems or hazel sticks which may remain in sight. If it happens that a large party is given in the autumn, the autumnal tints on the leaves of some of the Vines, such as West's St. Peter's, Barbarossa, and several other varieties, produce a magnificent effect. Pot Vines may be had in establishments where there are sufficient forcing pits all the year round; they are useful for forcing for the first and second crops of Grapes, a circumstance which renders the early forcing of permanent Vines unnecessary, and which saves much time, labour, and money. I always think it a pity to force permanent and well-established Vines before the beginning of January; the latest succession Grapes (in gardens where there is no stint of forcing-houses) may be produced from Vines in pots, and, by so doing, growers will be enabled to do full justice to their permanent Vines. Every practical gardener knows how detrimental it is to leave Grapes on permanent Vines after the month of January; the French mostly cut all their late Grapes off the Vines in the month of November. I was at the late Baron James de Rothschild's, at Ferrières, a few years ago, in the month of January, and there I found that all their late Grapes had been cut, and that the stems were placed in bottles containing charcoal and water, having been severed from the Vine about two months. I have stopped the bottles with Portland cement to keep the atmosphere from the water, and it has answered well; unfortunately, few gardeners have convenience to do this.

J. MEREDITH.

Garston.

PEARSON'S GOLDEN QUEEN GRAPE.

SOME years since, hearing that the native Grapes of North America enjoyed a comparative immunity from the attacks of mildew, I resolved to cross one of them, the Strawberry, with our hot-house varieties. I raised about a hundred seedlings in this manner, using in every case the Strawberry as the female parent. Many of my friends will remember the interest this experiment created at the time, from the extraordinary character of the foliage produced. The Strawberry Grape has small woolly leaves, very little cut, indeed nearly heart shaped; the seedlings were all deeply cut, some of them small, and some of immense size. I remember the Rev. C. Peach, of Malton-le-Street, asking me for a leaf as a curiosity, which was

some inches bigger in diameter than a page of the *Times*. The fruit of these seedlings varied as much as the foliage, being of all colours, and, I may add, of every degree of bad flavour, except one or two, which were golden in colour, and very sweet. Of these I chose one only to keep, which was exhibited in London, August, 1870, and under the name of Ferdinand de Lesseps, received a first-class certificate, which it richly deserved, not so much as a new Grape, as a new fruit altogether. With me it is a strong grower, an abundant bearer, and of a beautiful golden colour. The fruit being scented with Strawberry, and tasting like barley-sugar flavoured with Pine-apple, according to some, and like new honey, according to others, is totally unlike that of any other known Grape. Here was, at least, a great curiosity, a pretty scented fruit, which few with their eyes shut would take to be a Grape. But every one does not like barley-sugar, or new honey either, and then, unfortunately, the berries were little larger than those of the Frontignan, and the bunches scarcely so long; and, though Ferdinand found many admirers, I never recommended anyone to plant it who had not seen and tasted it. I next tried what the effect of crossing Ferdinand with other Grapes would give, and raised another large batch of seedlings, some also from other crosses, which were all planted together. Some of these were exhibited September 6th, 1871. From them the Committee of the Royal Horticultural Society selected one for a first-class certificate, and which I named Dr. Hogg. Now I had great doubts about the value of this variety, and told the committee so. I knew it was a seedling from the Duchess of Buccleugh, and never could make up my mind what was its other parent, or if it had been crossed at all. Knowing that all the race of Grapes, comprising Muscat Muscadine, Chasselas Musqué, Joslin's St. Albans, which were the result of a cross between the Muscat of Alexandria and Royal Muscadine to which the Duchess of Buccleugh belongs, were, though very high-flavoured, dreadfully subject to crack, I feared the same might be the case with mine, and never would recommend it to anyone. Besides growing in a north border of a Geranium-house, it never was very well ripened, and appeared not to retain its high flavour after it was ripe. Now, however, when it is out, and in other hands, as many no doubt have heard, it is proving one of the best Grapes in cultivation. With me it has never cracked a berry, and whilst quite equal in flavour to the Duchess of Buccleugh, is twice the size, bunch for bunch. The Golden Queen, to which a first-class certificate has been awarded, is a seedling between Ferdinand de Lesseps and Black Alicante; it fruited for the first time last year in a pot, standing on the border of my Fig-house; finding that it had made a root through the bottom of the pot, I broke the pot to pieces, and "billed" up the ball with fresh soil. No one expects a Vine that has fruited in a pot to do much the following year, but to my surprise this has carried thirteen bunches perfect in every respect this season. The bunch and berry are exactly alike in shape to the Madresfield Court, but in colour it is a bright gold. The flavour is that of a Muscat of Alexandria without any of the aroma peculiar to the Muscats, being, in fact, a rich, fleshy, sweet Grape. The foliage shows its hybrid origin, being strong, dark looking, and feeling to the touch more like that of a Fig than a Vine. The wood is bright cinnamon in colour, and taking fruit and Vine together, it is perhaps the most beautiful Vine ever seen growing. From the large amount of water used in the Fig-house, and the little heat employed, mildew attacked most of the Vines in that house, but the robust foliage of this variety appeared almost mildew proof. Lastly, only two kinds under these unfavourable circumstances were really ripe in this house, and the Golden Queen was one of them; many have only half-ripened their wood, and the thinnest shoots of this are as dark in colour, and as hard as the thickest. At the time the above was written the keeping qualities of Golden Queen could only be inferred, but fruit remained on the Vine in good condition till it broke into leaf this spring, proving it to be a worthy companion for the best of the black keeping varieties. This Vine has this year carried sixteen bunches, the best of which I sent, at the request of M. Van Houtte, to Ghent, to be figured in his "*Flore des Serres*;" some to the Royal Horticultural Society's fruit committee, to let them see that it maintained its character; and others to various eminent horticulturists, and no one, as yet, has pointed out a fault either in the habit of this plant or its fruit.

Chilwell.

J. R. PEARSON.

Efficacious Remedies for the Vine Pest.—The Abbé Moigné says that two remedies, or rather two insect-killing substances, have proved to be efficacious in destroying the Phylloxera. In Cognac, M. Mouillefer, professor at the Agricultural School at Grignon, and delegate to the Academy, has tried with success the sulpho-carbonate of potash, proposed by M. Dumas. In the proportion of one-thousandth dissolved in a litre of water, this solution proved quite harmless to the plant; but at the end of a few days, by the toxic vapours

it disengaged, it was able to mete out prompt justice to the devastating insect. But it was expensive, and it was necessary to find a means of manufacturing it economically on a large scale. This problem was scarcely proposed when it was solved. It was the employment of alcohol that rendered the preparation of this salt slow and limited to small quantities. M. Valancecimes, director of the works at Dorrvaux's Centrale Pharmacie de France, at St. Denis, found that by reacting with strongly-concentrated sulphide of carbon upon carbonate of potash, its transformation into sulpho-carbonate could be effected directly without the intervention of alcohol. MM. Romein and Petit, at Nîmes, and M. Balbiani, at Montpellier, on their side, tried coal-tar, and with entire success. The proportion of coal-tar required—several thousand kilogrammes to the hectre (2½ acres)—seems at present enormous; but, by a judicious distribution of the substance, there is no doubt that the quantity may be considerably diminished.

Fruit of Tacsonia Van Volxemii.—I cannot agree with your correspondent as to the agreeableness of this fruit. In addition to that species, I have now in fruit *T. eriantha* and a variety sold to me under the name of *T. hybrida multiflora*; also *Passiflora acerifolia*, with fruits like black Grapes covered with a fine bloom; *P. cœrulea racemosa*, fertilised with *P. cœrulea* (this variety will not set with its own pollen), *P. Impératrice Eugénie*; another with deep purple flowers, the name of which I do not know; and *P. cinnabarina*, otherwise known as *Disemma coccinea*. In past days I have fruited many other members of this favourite family of mine, but have failed to find amongst them all a fruit even passably palatable, excepting, perhaps, *P. edulis*. With the tropical *Granadillas* I have had no experience. That they all might with impunity be eaten, I have no doubt. It is to be regretted that the Australian *P. cinnabarina* is not an agreeably-flavoured fruit, as it bears so abundantly with little or no care, and the fruits are very succulent; their smell, when ripe, is not unpleasant, but the taste is insipid. Whether they could be utilised by conversion into a "rob" or jam would be worth a trial, which I commend to the professors of the cuisine.—J. M., *Hatchchurch, near Arminster, Devon.*

The Beurre Clairgeau.—This is a well-known and favourite dessert Pear in Jersey, and Mr. Pond, a neighbour of mine, has one of the best specimens of it with which I am acquainted. His tree was planted eight years ago, and is grafted on the Quince. The second year after planting, it produced a Pear weighing 1 lb., and it has since continued to bear very fine fruit, no Pear having been picked from it, less than 1 lb. in weight. This year it bore thirty-five splendid Pears, weighing 56 lbs. The soil in which it has grown, is a deep sandy loam, and the tree has been watered with liquid manure in dry weather. André LeRoy in his "Dictionnaire de Pomologie" says this Pear is a moderately vigorous grower, and a great bearer. The fruit has a white flesh, which is melting, juicy, and not very gritty, the aroma being agreeable and delicate. It is very variable, however, as regards both shape and quality; although sometimes second-rate, it is generally first-class. Its size is always large; in 1851 the Horticultural Society of Paris awarded a medal to a large and fine fruit of it. As regards maturity it seldom ripens before October, and rarely keeps beyond the first days of January.—RUSTICS.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Stephanotis floribunda in Fruit.—I have at present two large fruit on a small plant of the *Stephanotis* in my stove; they are not yet ripe, and have been on the plant for nearly twelve months; they are still a bright green, and have not increased in size for some months.—FRANCIS J. GRAYSON, *Coel Angler, Co. Tyrone.*

How to make a Fruit-room ornamental.—My fruit-room is 70 feet long, staged all round, and has a centre stage running its full length. On this stage or table light-coloured Apples, such as Wellingtons and Golden Nobles, are laid in the form of diamants, the shelves being incited by high-coloured kinds, with a circular patch in the middle of each diamond. Few flower gardens in summer, much less in winter, can vie with this arrangement.—KIRCHENBERG.

Excrescences on the Roots of Peach Trees.—I send you part of a root of a Peach tree in the hope that you will be able to tell me what the knots on it are, from what cause they appear, and what the remedy for them. The tree has been planted against a south wall two years in a good rich border. The roots are all like the one sent, and the tree has made no wood to speak of, whilst three others planted against the same wall have grown remarkably well this year. They have all been well supplied with water during summer.—E. J. R. [The specimen sent is very curious. It shows an attempt to throw out adventitious buds, which first protrude the inner bark, so as to make it look like a case of false Fungus.]

The Peach Nut.—A fruit, answering to the description of the Peach Nut (see p. 349), was, some three or four times, offered to me in Spain, under the name of *Frasquilla* (I write from sound, for I never saw the word in print). I was struck with the delicious flavour of the fruit, and, upon making inquiries respecting it, was told that it was a hybrid, produced by grafting a Peach upon a Pomegranate stem; this would, doubtless, account for the Pomegranate colour and Peach flavour of the fruit. I imagine it to have been rare at the time I was in Spain (1869), for, though I was liberally supplied with most fruits, I remember receiving but three or four *Frasquillas*.—J. M. WOODWARD.

INDOOR AQUARIA.

THE annexed illustration cannot fail to show how highly interesting a portable aquarium and plant case combined may be made when properly fitted up and arranged. Such combinations possess an interest peculiarly their own, and although their value may be unappreciated by those who possess gardens and plant houses, yet such cases of living interest are admirably suited to invalids and persons living in cities. Even in the most unfavourable localities for out-door vegetation, such indoor gardens may be replete with beauty alike secure from vicissitudes of weather or atmospheric impurity. Indeed, of all forms of vegetable life, aquatics or sub-aquatics, are best suited for indoor gardening in towns; but if the best results are to be obtained from such a pursuit, a commencement must be made under the direction of some one acquainted with the arrangement of a bit of rock-work suitable for such cases, the kind of plants with which they should be furnished, and the best material in which to grow them. For cases like that now represented hundreds of rare and beautiful plants are suitable, and also plants neither rare nor costly, but yet not less interesting. Many Grasses, Sedges, Cyperus, and Ferns grow well in such cases if elevated an inch or two above the water level. For submerged vegetation we have *Valisneria*, *Anacharis*, *Charas*, the pigmy-blossomed *Water Lily*, the Hawthorn-scented *Aponogon distachyon*, fresh green disc-shaped sheath-rooted *Duckweed*, *Pontederia crassipes*, the hollow petioles of which are swollen and filled with air, and many other equally interesting plants, all of easy culture. In the hands of an experienced cultivator, many rare plants would thrive as well in a case like this as in a cool plant-stove; and then *Sarracenias*, *Cephalotus*, *Dionæa*, *Droseras*, and even one or two of the true Pitcher plants, as *Nepenthes phyllaphora* or *N. gracilis*, might be added, notwithstanding their reputed carnivorous tendencies. Given a few lumps of fibrous peat and a handful of fresh living *Sphagnum*, and even the gorgeous crimson-winged *Disa* might be induced to display its rich colours and fresh glossy foliage. Plant life, too, may be interestingly associated with animal life. In the water may be lizards, golden and silvery carp, brown-speckled and green frogs, and a whole colony of water-beetles and snails; while, flitting about overhead among the plants may be butterflies of many hues, and a few of the most showy kinds of moths. Are we, then, to capture such insects on the wing, and introduce them? No, they must be bred in their new home, and this simplifies the whole affair, for specimens of all the more showy butterflies may be bought at almost any naturalist's, in the chrysalis state, for at the most a few pence each; and these, if placed in a little box (without a lid) of dry earth, and introduced to the plant case, will "come out" in due season, like other butterflies, and will delight us with their elegant forms and brilliant colouring. Even the common white speckled garden-spider added to such a case tends to give it life and interest. This aquarium is divided into two parts; the lower one, as will be seen, for water, fish, and true aquatics; the upper one for sub-aquatics and other plants. B.

Kerr's Vaporising Stove.—We (the *Irish Farmers' Gazette*) have in operation that very ingenious contrivance for burning paraffin, crystal, or rock oils—namely, "Kerr's improved vaporising greenhouse stove." This little stove is very simple, portable as a stable lantern, and fed and trimmed with as much facility as an ordinary lamp. Each is provided with a vaporising dish somewhat on the Polmaise principle to hold water; through the centre of the dish the heat passes, and carries with it a portion of vapour, thus obviating the atmospheric aridity which in many instances, in plant-houses, especially, is so much to be deprecated. When working, this stove does not appear to give off, in the least, anything in the shape of either smoke or sulphurous irritant gases, unwholesome to animal or vegetable life. In fact, on the contrary, we are assured by Dr. Cameron that the heated air diffused by this stove is such as would serve, rather than injure, plants. For these small unheated greenhouses attached to town dwellings, one should think this neat, cleanly, and portable little contrivance would be well adapted and quite capable of keeping King Frost at bay. These stoves illuminate as well as heat. One of them will burn for twenty-four hours without attendance, at a cost of about threepence.

AN AQUARIUM AND PLANT-CASE COMBINED.

GARDENING FOR THE WEEK.

AND AMATEUR'S CALENDAR.

Hardy Flowers, Alpine Plants, and the Wild Garden.

We have now entered on that season of the year when Nature herself appears to have the utmost difficulty, even under the most favourable circumstances, in finding the necessary material wherewith to complete the hybernal link in Flora's chaplet. The few flowers that betokened her late autumnal but declining vigour have been sadly marred by two consecutive nights when the thermometer indicated some 12° of frost, and, covered as the ground now is with snow; we will leave the flowers at rest under it for the present. Rest, however, to the flowers does not by any means imply rest to the cultivator; he has his work to do even at this dull season. We will presume that the dead and dying tops of all his herbaceous plants in the select borders have been by this time removed and deposited in the most out-of-the-way place available, ready for the crematory process previously described. In the wild garden such a clearance is, however, unnecessary; as I before said, leave these souvenirs of the past, as Nature intended them, to form a protection, and to aid our future prospects. What, then, is to be done with the borders thus cleared? The usual practice is to give them a dressing of manure and then dig them over. That this is the best form of practice I very much doubt. With the process of digging, the idea of a spade is naturally inseparable, but that very implement should be all but proscribed from borders of this class, except in so far as planting is concerned. My advice is, to first hand pull all the larger weeds; these will have gone ahead since hoeing and raking became impracticable; carefully remove such as are growing about the crowns of any of the plants—too often are these passed over during the summer clearings—but they are liable to injure, by their dense growth, the more slender growing occupants of the border. Having so done, a nice dressing of old thoroughly well-rotted manure should be distributed, or, what I believe to be better still, a concentrated manure, such as may be made by mixing "night soil" with the burnt ashes—resulting from the burning of all the old rubbish—these ashes constitute not only a most perfect disinfectant, but are equally potent and absorbent, and a small quantity goes a long way; where earth closets are used, the accumulation of the season, after being once or twice turned over, will answer the purpose admirably. A sharp frosty morning, it may be added, is the very best time for preparing this material. This done, a nice dressing of fresh loam, just sufficient to cover the manure, may be applied; or, failing that, the surface should be turned over to a depth of 3 or 4 inches, for which purpose nothing is better than one of Parkes' five-tined steel forks, all the more suitable when it is nearly worn out. This advice may frighten many people who believe in deep digging, trenching, and what not; and, he it remembered, that I am no disbeliever in these operations as applied to general culture. My experience clearly leads me to the conclusion that, after the border is planted, deep digging means wholesale slaughter of roots and, not unfrequently, of plants also; added to which, all herbaceous plants (peat-loving ones excepted) like a firm soil to root in. One of our borders has not been dug for twelve years, receiving nothing beyond a dressing of manure, topped up with a little fresh soil each year; and, in spite of its hardness, the plants thrive wonderfully. That there is a time for deep trenching I hope to show when I deal, in a week or two, with the formation of one of these borders. Such plants as herbaceous *Lobelias*, *Tropaeolum tuberosum*, some of the tenderer *Oxalises*, *Linum narbonneuse*, *Tritonia aurea*, *Tricyrtis hirta*, the New Zealand *Flax*, and such plants as are of at all doubtful hardiness, should be protected by two or three shovelfuls of light leaf mould or ashes placed above or around them. The leaves of all *Yuccas* should be tied together with a few thick strands of soft matting, so as to prevent the snow from damaging the centre growing bud, and otherwise destroying their generally graceful contour; this, if not already done, should be seen to at once. The Aloe-leaved *Yucca*, with its beautifully variegated form, though generally esteemed tender, may be further protected by a good thick straw rope twisted from the ground to the extreme tip of its leaves and tied to a stake; a few shovelfuls of leaf soil over the root will prevent the frost from penetrating the ground; and, under these conditions, it will stand any ordinary winter. All Alpine plants in pots will now have been securely planged in ashes or stowed away in frames; the former will require little attention beyond keeping a sharp eye for slugs. It is by no means a bad plan where large numbers are grown in pots, and wherever a collection or even a selection is cultivated (it is always advisable to have a reserve army to fill up gaps that are sure to occur), to have at the bottom of the border wherein they are to be planged a layer, of say 3 inches, of rough home-made asphalt; with a good slope from back to front,

this is a capital preventative to worms, which often play havoc by loosening the roothold of slender growing plants. In the process of plunging always have a few labels by you, as you are sure to find some that have become decayed or so far obliterated that before spring they will have become illegible. Those in frames should have the lights thrown off every day when it does not absolutely freeze or rain—so as to keep down damp—which is much more to be dreaded than frost with this class of plants; a few slices of Potato may be placed among the pots with advantage; turning them over on a fine day is sure to yield a harvest of slugs, especially the small ones, which otherwise are troublesome to find, as they generally retire into the interstices of the soil or down the sides of the pots after they have completed their nocturnal depredations. Where Alpine plants are grown in a natural way on rockeries, it is a capital plan, after the trimming and weeding, which I will presume has already been done, should a heavy fall of snow occur, to heap it on the rockeries, bearing in mind that you cannot put too much on; it is the true protection which Nature affords her Alpine children in their native habitats, and no better one can be found. The same practice may be very beneficially adopted with ordinary frames, banking the snow lightly round the sides.—JAS. C. NIVEN.

Flower Garden and Pleasure Grounds.

With the exception of occasional sweeping and rolling of gravel walks, lawns, and Grass belts or verges, little for some time to come will be required to be done in these departments, except in cases in which alterations of groundwork of any kind is in progress; and, wherever such work is in hand, it should be pushed forward with all possible expedition. In the meantime, take advantage of the early part of frosty mornings, whenever they occur, to get forward with any kind of work which will necessarily involve wheeling, carting, or other heavy traffic; and, wherever it is necessary to do this upon lawns or greensward of any kind, planks should always be used for wheeling upon. Laurels and other evergreen shrubs in conspicuous situations may have dead boughs removed from them, but all extensive cutting back or pruning of live wood should be deferred until spring or until all danger from severe frost is over. Many hardy berry-bearing plants, the fruit of which is getting ripe, are becoming very ornamental, such as the *Crataegus Pyracantha* or evergreen Thorn, *Cotoneaster Simmondsii* and *microphylla*, *Skimmia japonica*, and others. Wherever, however, birds abound, it will be necessary to protect them by means of a net or otherwise, or they will quickly disappear. The greenfinch, and some other hard-billed birds, disfigure the berries to get at the seeds, while the blackbird, the thrush, and the missel thrush swallow them whole. All such hardy plants as *Magnolias*, *Pomegranates*, *Ceanothuses*, and Tea-scented *Roses*, trained to walls or pillars should at once receive a thin thatching of straw, dry Fern fronds, or some similar protecting material; while such winter-flowering plants as the *Chimonanthus fragrans* and the *Jasminum nudiflorum*, which in sheltered situations are now coming into flower, and to which it may be desirable to have free access for the purpose of gathering the blooms, should be protected by means of a moveable curtain of frigi domo or mats. In order to ensure, also, the safety of such plants as the various sorts of *Yucca*, *Tritoma*, &c., which may be growing upon lawns or on the margins of shrubbery borders and similar situations, place a portion of straw, dry Fern, or any other littery matter round their base, keeping it in position by means of a few boughs or pegs fixed over it. The surface of beds containing the roots of *Fuchsias*, *Erythras*, *Aloysias* or Japanese *Lilies*, should now be covered to the depth of 3 or 4 inches with sawdust, old tan, or cinder ashes. Place hand-glasses, small frames, or cloches, upon well-established plants of the Christmas Rose in order to obtain fine pure white blooms of it with long flower-stalks. Let the tubers of *Dahlias* and the bulbs of *Gladioli* be safely stored in some dry situation out of the reach of frost. Attend to the wants of bedding plants; exclude frost by covering them up, or, what is better, if possible, by the moderate use of fire heat, and get, as soon as possible, the entire stock of plants placed in structures furnished with the means of supplying this necessary desideratum.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

In protecting standard *Roses*, worked on the Briar, all that is necessary is to bind some hay or soft straw round the head where budded or grafted. In the case of dwarf *Roses*, some hay, straw, or rough litter, shaken lightly over them, will be found to be sufficient protection. If a Rose tree, which has got frozen over night, is sheltered or covered over the following morning before the sun reaches it, it will be found that in nine cases out of ten it will be saved. The part which requires most protection is the point of union between the graft and the stock. I have examined many Rose trees that have been killed by frost, and have always found that failure

occurred at that point. Some Rose trees, which I planted under the shade of a north wall, have never required any protection, for in winter they are never subjected to sunshine, and are often frozen for a week or ten days together; yet, when the frost is gone, I have found them to be uninjured. These have been planted in order to secure a few good flowers for about three weeks, during the later part of July and beginning of August. The first bloom of Roses is then over, and, where a large supply is required, trees thus situated yield some fine fresh flowers, while others, in exposed situations, are burnt by sun-heat.—H. G.

Orchids.

The bright scarlet flowers of *Sophranitis grandiflora* contrast strikingly with those of other Orchids of more delicate colours that are also now in bloom, such, for instance, as *Lycaste Skinneri*, *Calanthe vestita*, *Veitchii*, *Palumna fragrans*, *Cypripedium insigne*, *C. venustum*, *Dendrobium moniliforme*, *D. heterocarpum*, *Odontoglossum Hallii*, *O. Pescatorei*, *O. Bluntii*, and *Oncidium aurosum*. In order to preserve the blooms of these as long as possible free from spotting and in good condition, those unprovided with a show-house should place them at the dry end of the ordinary Orchid-house, in a temperature varying from 55° to 60°. *Lycaste Skinneri* is one of the best winter and spring-flowering Orchids which we have, and, when well grown, yields abundance of bloom, which is useful for cutting. It will grow well in a temperature varying from 60 to 65°. *Cypripediums* are also useful in the way of furnishing cut bloom; and, where many varieties are grown, a supply of flowers may be had throughout the year. When growing, these Lady's-slippers require abundance of water; they should be potted in manure from a spent Mushroom-bed, sharp sand, charcoal, and a double quantity of not-too-fibrous peat, the whole placed over efficient drainage, and set in a temperature of from 60° to 70°. *Celoglyne cristata* will require less water than has hitherto been given it; and, as the flower-spikes appear, the syringe should not be used, but sufficient water must be given at the roots to prevent the bulbs from shrivelling. Little potting need be done this month; but time may be profitably spent in sponging and cleaning the plants from dirt or insects.—E. CULLEY.

Indoor Fruit Department.

Vines in pots which may have been plunged in bottom-heat, in order to promote growth, should be removed and set on a hard bottom, such as a wooden shelf or on a board placed on the top of hot-water pipes, as soon as their shoots are from 2 to 3 inches in length; and such rods as may have been suspended in a horizontal position, in order to ensure a more even break, should be tied into their permanent places before the young growths have become more than 3 inches in length. The weakest shoot from such buds as show two growths should be rubbed off, leaving, however, the one which shows the best indication of a good bunch. Permanent Vines started about the beginning of last month will now be swelling their buds. These should also have their tops tied up, and the temperature may be increased 5° above that previously recommended. Continue to stir up the fermenting material which rests on the inside border, and if the heat is beginning to decline add a little fresh material. Care should now be taken to prevent cold air from entering the early Vinery. It is often of great advantage to stuff all crevices about the ventilators, underneath the doorway, &c., with the view of maintaining a uniform temperature when the exterior cold is excessive. In many instances the earliest Vinery will be started about the first of December, and former directions may be applied in such cases, but a little fire-heat will now be required from the first. Queen Pines which have been resting with the view of obtaining early fruit will now require particular attention. To have fruit ripe in May the plants must be started into growth at once. Where there are large quantities to choose from and only a dozen or two wanted as an early batch, those most open in the centre should be selected; tie the foliage of such plants carefully up in order to prevent them from getting broken while being removed; take off all the small leaves at the base of the stem, remove all the loose soil well down to the root, and top-dress with a mixture of strong loam and horse droppings; into this a mass of young roots will soon be emitted. If the plunging material is much exhausted most of it may be taken out and new material substituted, but the heat is produced in a more desirable way when a little of the old is mixed with the new. In plunging, set the plants at convenient distances apart, according to size; press the plunging material firmly about the pots, as this, when new, generally falls away very much before the fruit is ripe. Bottom-heat should be allowed to rise until it reaches 90°, when care should be taken that it does not exceed that point. A slight watering should be given to settle the fresh top-dressing down amongst the old soil, but do not give a thorough soaking until the heat is up, when every particle of the ball should be

moistened with water not cooler than the bottom-heat; keep the atmospheric temperature for these at 70° by day and night with fire-heat, allowing 10° more during sunshine.—J. MUIR.

Hardy Fruits.

Cherries are universal favourites, both for pies and dessert. Among the finest varieties may be named Governor Wood, perhaps the very finest in flavour; White Heart, Werder's Early Black, Waterloo, Monstrous Heart, Downton, Buttner's Black Heart, Bigarreau, Frogmore late Bigarreau, Early Rivers, and Transparent. Then among free growing and fruiting kinds there are a whole host of Dukes, Kentish, Florence, Early Purple Gean, Morello, Bedford Prolific, and Belle Agathe, the latest of them all, which it is said the birds will not eat. Of Peaches it is difficult to beat such varieties as the Royal George, George the Fourth, Noblesse, Barrington, Grosse Mignonne, Teton de Venus, Bellegarde, Violette Hâtive, Chancellor, Rivers, Early York, and Early Alfred, Lord Palmerston, Prince of Wales, Late Admirable, and Salway. Among Nectarines may be taken Rivers' Pine Apple and New White, Pitmaston Orange, Elruge, Downton, Hardwicke Seedling, Violette Hâtive, Balgowan, Humboldt, Stanwick, and Newington. My favourite Apricot is the Kaisha, the quality and flavour of which is as much superior to those of most Apricots as a Green Gage is to other Plums. It also makes the most delicious preserves, and the tree seems hardier, and escapes the spring frosts better than other varieties. The Moor Park is no doubt the next best, and only those in search of variety now care to grow such varieties as the Breda (said, however, to be best for a standard), Red Hemskerk, Roman, Royal Peach, or Turkey Apricots. Apricots are wonderfully well adapted for growing on cottage walls or gable ends, and do exceedingly well in such positions when left to grow in a free manner, without much pruning, in the form of half standards. Mulberries, white and black, should be planted much more plentifully than they are. When they arrive at a considerable age they mostly fruit freely, and the fruit is in universal favour with high and low for pies and preserves. They do best in rather sheltered situations, and in the rich warm dark coloured soils of old kitchen gardens.—D. T. FISH.

Kitchen Garden.

It is advisable to make a sowing of Cucumbers now, in order to furnish plants for putting out about the middle of next month, and if the seeds are soaked in warm water for fifteen or eighteen hours they will germinate much quicker than they otherwise would do; place the vessel containing the seeds on or near the hot-water pipes, so as to secure a steady temperature of 85° or 90°. I have frequently soaked them thus till the seeds sprouted, when I wanted to push the plants on, and when afterwards planted in pots of warm light soil the plants have appeared in three or four days. Almost every grower has some favourite Cucumber for early forcing; but I may mention that for the supply of a family Telegraph is a reliable variety. Where, as in many places, glass structures are limited, Cucumbers may be successfully grown in pots or boxes in any house in which a suitable temperature is kept up, such as one in which flowers are forced. They may be elevated on back shelves and the shoots trained over the pathway or down the rafters. Thus treated they do not obstruct light from plants underneath them. Where new Potatoes of good flavour are required early, a few selected tubers of the old Ashleaf or any other good early variety may be potted in 48-sized pots, one tuber in each pot, and placed in a Vinery or Peach-house just started. Never allow more than one shoot to grow from each tuber; more growth only tends to produce small tubers and retard maturity. When they come up, and before they become pot-bound, either plant them in a prepared hot-bed, or pot them into larger pots, with the view of growing them on in the house till the crop is fit for use. I prefer the former plan, when it can be conveniently done; but a fair amount of success may be obtained by the latter method, if the pots can be placed in a light position—success or failure depending, in fact, in a great measure, upon this; have all leaves raked up and stacked in a convenient place for making hot-beds, as the season advances. Oak leaves are the best for this purpose, and most lasting. If early Radishes and Carrots are required, a hot-bed may now be made up for them, composed of about equal portions of leaves and stable-dung; and, when the heat has become steady, apply about 5 inches of light sandy soil, and sow early French Horn Carrots in shallow drills 6 inches apart, and afterwards scatter thinly a few Radish seeds all over the surface. The Radishes will be drawn before the Carrots require the space. Whenever severe frost sets in, and it becomes necessary to use protecting materials for Celery and other crops, the plants should always be allowed to remain covered till everything is completely thawed.—E. HORDAY.

THE ARBORETUM.

BONAMY'S WEeping BIRCH.

THIS remarkable form of the Birch was raised by Messrs. Bonamy, of Toulouse, and was first shown by them about eight years ago. Our figure (from the *Revue Horticole*) gives a good idea of the habit of the tree. In the old variety of Weeping Birch, the branches fall with so perceptible a curve as to give a rounded appearance to the upper part of the tree; but, in this new Weeping Birch, each branch hangs down almost perpendicularly, forming an acute angle with the trunk. This peculiarity gives to the tree a veritable weeping aspect,

A new Weeping Birch.

which is enhanced by the flexibility of its swaying limbs, and the varied tints of its foliage.

FERTILISING AUCUBAS.

THERE is one condition which is quite essential to the successful fecundation of a plant, that is, that the male and female organs attain their perfect development at the same time, and this is almost always the case, when both organs are found in the same flower. It is otherwise, however, with Monoecious or Dioecious plants. Of this, the Aucuba is an example, and, although in its case it is quite possible for fecundation to take place naturally, it is desirable to give assistance in order to ensure the production of a quantity of fruit. The male plants have a small four-toothed calyx, a four-petaled corolla, and four short stamens alternating with the petals. The females have (instead of the stamens) an inferior one-celled ovary, surrounded by a fleshy epigynous disk, the style short, thick, and tumid at the base, the stigma orbiculate, and the ovary containing a single ovule. The fruit is a one-seeded berry. The flowers are insignificant. Female plants were first brought into this country; no fruit was therefore seen until the introduction of male plants by Mr. R. Fortune in 1861. The berries are very beautiful, of a bright coral red, and are borne in profusion, rendering the bushes exceedingly ornamental. The male flowers are small, and, as they generally

open before the female ones, it is desirable, in order to secure a good crop, to place the latter plants in frames or other forcing houses that they may flower as early as the male plants, and so be ready for fecundation at the same time. Another method is to collect the pollen from the male flowers and store it carefully for use, as it retains its vitality for a considerable time. Amateurs (I speak from experience) may obtain good pollen from any of the principal nurserymen. I procured a shilling packet from Mr. Standish, of Ascot, and artificially impregnated my plants. I watched the flowers open, and with a camel-hair pencil placed a small portion of pollen on the style; in the course of a day or two it was apparent which of the blossoms had been successfully fecundated. I obtained in this manner a quantity of berries. The Aucuba is a very ornamental plant; it is better to grow it in small bushes for table decorations, its glossy green foliage and splendid berries rendering it exceedingly attractive; it is very useful in the flower garden, as, being quite hardy, it may be employed to fill up the beds from which summer flowers have been removed. It is of vigorous habit, and has the merit of enduring and even thriving in the atmosphere of our crowded towns and cities. The *A. japonica* bears the brilliant red berries of which I have spoken; its leaves are sometimes variegated, and blotched with pale yellow. In the *A. himalaica*, another variety, the berries are orange-red, the foliage wholly green.

W. N.

JAPANESE VEGETABLE WAX TREE.

THE *Japan Mail* contains some further particulars respecting the preparation of the vegetable wax produced in Japan, and chiefly exported to England. This wax is obtained from the fruit or, more correctly, berry of the Wax tree. The tree, which is a species of *Rhus* (*R. succedanea*), flourishes more especially in the southern provinces of the empire. The fruit, which usually ripens about the month of October, is gathered when ready, and cleansed from its loose outer husk, a process which is accomplished in large wooden vessels with wooden malls, similar to those in use for cleaning Rice. The residue product, available for the manufacture of wax, is a Bean-shaped kernel of the size of a Lentil, possessing an unusual degree of hardness, of a dark yellow wax colour, and offering a saponaceous exterior to the touch. The kernel is subsequently exposed to a sufficient degree to the steaming process, which deprives it of its extreme hardness, and allows of its oily properties being more easily extracted in the pressing stage. In this process the oil is received into small earthen vessels, in which it subsequently hardens to a bluish-green mass, in the shape which it is commonly met with in home consumption. Wax so produced is impure, and is only suitable for certain descriptions of candles and for wax-thread manufacture for home use. In order to render it merchantable for the exporter, the following refining process is resorted to:—The wax is boiled with a lye until it is brought to a perfectly fluid state, and is then drawn off into a reservoir filled with clear water, the pure wax, which floats upon the surface, being removed. The mass is then exposed to the sun's rays for a period of fifteen or sixteen days, during fine weather, for the purpose of bleaching it, at the expiration of which time the wax presents a dirty white crumbling appearance and a strong tallowy smell. The boiling and bleaching are repeated with the view of rendering the refining process still more complete, the only difference being that, instead of lye, pure water alone is employed in boiling it. The product is a clear white powder, which, in place of its former crumbling appearance, has assumed an almost crystalline formation. The last stage of preparation for export consists in rendering the powder a compact mass, which is effected by melting it over a fire with a little water (in order to avoid burning), and running it off into flat vessels. The product thus obtained, and known to commerce as vegetable wax, differs exceedingly from white beeswax, with which it possesses the properties of colour, brittleness, and similarity in its fan-shaped fracture in common. The only characteristic difference may be said to be in the odour, the beeswax giving off a refreshing aromatic scent in burning, while the tallowy smell of the Japanese wax is far from being agreeable. Vegetable wax is chiefly used in England in the manufacture of wax candles.

The Pepper Tree.—When in Nice one winter, I was greatly pleased with some evergreen trees growing in the public gardens there, called the Pepper tree, the botanical name of which is *Schinus Molle*. Can you inform me if this tree is hardy in England, and where one can be seen growing, and to what country it is indigenous? I have seen it also in Naples and Palermo, where, if I remember, it grows even larger than at Nice—say, from 20 to 30 feet in height.—E. W. GERE, *Sandhurst Villa, Leamington*. [The Pepper tree is a very

graceful object in warm temperate countries; but we have never seen it thrive out of doors in England. It may, however, live out of doors in some parts of Devon or Cornwall. It thrives in the cool fresh climate of San Francisco. In London gardens it grows freely as a greenhouse plant; but never assumes the graceful habit that it does in the warmer parts of the shores of the Mediterranean.]

The term "Fir Tree."—This is simply the popular name by which certain species of the genus *Abies* are known. As is usual with popular names, it is applied very indefinitely to different kinds of trees belonging to this genus in different parts of the world. Some botanists make three genera of the trees grouped by others entirely under one genus, but the latter divide this genus into two sub-genera, namely, *Picea* and *Tsuga*. It seems most proper to apply the term "Firs" to the sub-genus *Picea*. The *Abies* proper includes the Spruces; the *Tsuga* includes the Hemlocks or Hemlock Spruce; and the *Picea* the Firs proper. These grow mostly in cold climates. They include the Balm of Gilead Fir, the Noble Silver Fir, the Great Silver Fir, the Silver Fir, the Purple Cone Silver Fir, Nordman's Fir, and a great variety of others. In the Spruces proper the leaves are short, needle-shaped, and distributed around the branches, while the cones are nodding or pendent with persistent scales. In the Hemlocks or Hemlock Spruces, included in the sub-genus *Tsuga*, the leaves are flattened and petioled, and arranged as if in two rows. In Firs the leaves are somewhat in two rows, but the cones at maturity are erect, and the scales fall away from the supporting axis.—H.

The Best Time for Moving Evergreens.—Your correspondents differ greatly in their opinions as to the best time for transplanting evergreens, some advocating spring, some summer, and others autumn as the best time for moving them; while their combined experience goes to show that evergreens may be transplanted at nearly all seasons of the year, the winter months perhaps excepted. Nevertheless there must be a general best time for the transplanting of evergreens—a time when the life of the plant can be ensured, and when it can be moved without impairing or at most but slightly impairing its vigour. That time cannot be in the spring when the sap has already begun to move, because, even should the plant live, the check given to it by the cutting of its roots would impair its vigour, at least for the current year; and the same consequence in a general way, must, of necessity, pertain to summer transplanted trees, to say nothing of the danger belonging to the moving of some species of Conifers, the leaders of which are of so much importance. Autumn, therefore, is the best time for transplanting evergreens, say from the middle of September to the end of October, or more definitely still as soon (the weather being favourable) as the plants have made their terminal buds. Why? Simply because the sap of the plants has not then become inactive, and the soil is sufficiently warm to induce the formation of new roots, which serve to re-establish the plants in their new situations, thereby enabling them to push vigorously and without check the following season.—PROPAGATOR.

The Uses and Functions of the Leaf.—The office and utility of leaves are becoming better understood by cultivators than formerly; yet we find a good many still adhere to the old belief that the sun's rays directly shining on forming fruit are what perfect it, independently of other influences. On this subject, theory and practice have been invariably found in perfect accordance with each other. The principles of physiology teach us that the sap of a tree, when it passes in at the roots, remains nearly unchanged in its upward progress through stem and branches, until it reaches the leaves, where, being spread out in those thin organs to light and air, it undergoes a complete change, and thus becomes suited to the formation of new wood and new fruit. Strip a rapidly-growing tree of its leaves at mid-summer, and from that moment the supply of new wood ceases, and it will grow no more till new leaves are formed; and if it have young fruit, the growth and maturity of the latter will cease in the same way. A few years since, a Yellow Gage Plum tree lost all its foliage from leaf blight, when the Plums were not fully grown, and while yet destitute of flavour. The fruit remained stationary and unaltered, until, in a few weeks, a second crop of leaves came out. They then swelled to full size, received their crimson dots, and assumed their honied sweetness of flavour. The object of pruning should be, therefore, to allow the leaves to grow to full size without being injured from crowding. We find the following corroborative fact stated in a late number of the *New England Farmer*:—We once knew an intelligent lady strip her Grape Vines of a portion of their leaves, in order to let in the sun and ripen the fruit; but, to her surprise, where the leaves remained as Nature had disposed them, the Grapes were the earliest, and every way the best. This led her to investigate the matter, when she was delighted to learn that the leaves were not only the protectors, but the eaters of the fruit, constantly elaborating and supplying it with the pabulum it required to bring it to perfection.

THE MIGRATION OF USEFUL PLANTS.

LITTLE is known of the travels of the first plants of cultivation until at length we trace the fruits and cereals in Egypt, Carthage, Greece, and Italy, spots surrounded with a halo which time has not dimmed, visible landmarks in the history of man and of useful plants. Noah "planted a Vineyard;" and no doubt the Vine, with the Olive and other fruits, had crossed the fertile "wilderness" from Armenia to the shores of the Caspian, for it was only in the far East that the Vine, the Peach and the Fig, the Apricot and the Pistachio-nut, sprang unbidden from the fruitful earth. Other countries obtained them second-hand. Osiris presented the Vine to the Egyptians, and Bacchus distributed the Grape in those warm countries which a nude deity found it agreeable to visit; while other kind gods fetched the Orange from the Garden of the Hesperides, and planted it on the shores of the Levant. It seems that the Greeks obtained most of their fruits from the gods. The Olive, for instance, was produced by Minerva on some unknown spot, where Hercules found it and carried it to Greece, on returning from one of his expeditions. This may have been about the time that the golden implements of husbandry fell down from heaven on the banks of the Borysthenes. The practical Romans acquired their vegetables with the sword and spear, as Lucullus did the Cherry, which he conquered with Mithridates in Pontus; and whatever the Greeks had gained, supernaturally or otherwise, came to Rome, like the Cherry, by gravitation of conquest. Italy was poor in indigenous fruits, and probably had, at first, only the wild Mulberry, the Apple, Pear, and Plum, but she afterwards covered her slopes and plains with Olives, Oranges, Figs, and Vines, by energy and enterprise. We learn little of plants until long after the Greek Rhizotomæ or collectors of medicinal roots, Aristotle the pharmacopæist, and his pupil Theophrastus. Mago, the Carthaginian general, was an early authority, who wrote the first great work on agriculture, and Mago and Carthage were conquered, and his twenty-eight books carried to Rome, B.C. 146. At the same period stern Cato wrote only of useful plants, while Columella, at a later date, included a little fancy farming in his long discourse, and Dioscorides and Pliny treated of all known plants.

Distribution of Fruits.

The colonists and civilisers of the earth have been the distributors of its fruits. Even the commercial Phœnicians were among the early carriers, and advanced the Mulberry and silkworm from the furthest shores of the Mediterranean along the coasts they visited, by the same route over which so many plants have been conveyed from Nature's gardens in the East. The indigenous fruits of Europe were Crabs, Nuts, Berries, Masts, and Sorbs, the rest she obtained from their Asiatic birthplace, and in most instances *via* Rome, their great rendezvous in historic times. Of the Cherry we have spoken; the Apricot arrived there from Epirus; Apples, Pears, and Plums from Armenia; the Damson (Damascene) from Damascus; the Peach and Walnut from Persia; the Chestnut from Castanea, in Asia Minor; and the Pomegranate from Africa. The Fig-tree, which sheltered the founders of Rome when they were suckled by the wolf, had crossed with some early travellers from Syria, or from its halting place in Greece. Honoured in the future city, it was carried next the Vine in the processions of Bacchus; and modern abstainers from the worship of that god are no doubt aware that the corpulent deity derived his vigour from the sugared and succulent Fig, not from the Vine. The jealousy of the Athenians, which vainly forbade the exportation of the Fig, produced the economists, or informers called *sukophantai*, or discoverers of Figs, and gave us the word *sycophant*. A tree still more revered by Pagan, Jew, and Christian, was the Pomegranate, whose fruit was embroidered on the ephod, and carved on the porch of the Temple. Bacchus is said to have first twisted the dry, hard calyx adhering to the fruit into "the likeness of a kingly crown," thereby ambiguously keeping faith with a girl whose confidence he had won by promising her the crown which a diviner had said she was destined to wear. When at last she died of grief and hope delayed, the betrayer metamorphosed her into a Pomegranate tree, and affixed the crown to its fruit for ever. The device of Queen Anne of Austria was a Pomegranate, with the motto "My worth is not in my crown," and the French had a witticism, "*Quelle est la reine qui porte son royaume dans son sein?*" The Pomegranate migrated to Europe with the first flight of plants, and crossed to the West Indies and South America with the earliest explorers. It reached its furthest limits in high latitudes when monks conveyed it to a distant island in the northern seas, where it still ripens fruit of small size around London and under the shelter of the South Downs. But in our climate the juices of this famous fruit of the desert has no attractions, except to curious school-boys, and its thousand pips make it, in our estimation, a fit repast for blackbirds. It is in Egypt and Syria that its delicious acid can be fully enjoyed.

Distribution of Plants.

Man, especially the Roman, has been the distributor of plants, but climate governs their distribution, arranges their divisions, and sets limit to their migrations. The Romans could not borrow from the flora of the south so freely as we have borrowed from them, since the arborescent and evergreen character of vegetation towards the tropics renders it liable to be destroyed by a slight degree of frost at any period of the year, whereas the herbaceous plants and deciduous trees and shrubs of temperate zones escape the winter's cold by retiring from active contention with it. On the other hand our sun seldom scorches our vegetable visitors, unless they come from a land of mist, like the Sikkim Rhododendrons; but Italian summers are too hot for some of the plants from the north. The Romans collected everything that a splendid sky, without a tropical sun, permitted, and their gardens contained nearly all the vegetables now in use. They had even the Cauliflower, a highly artificial modification of the Cabbage, which is said to have been originated in Cyprus, where luxury kept a good gardener. In the days of primitive virtue, Cato restricted his account of the horticultural art to the cultivation of culinary plants, and of those used in chaplets; and the same spirit, dictating the laws of the Decemvirs, made *hortus* synonymous with *heredium* or inheritance (as it was practically to Naboth); and it made the families of the Lactucarii, Valeriani, and Fabii proud of their names. Taste became less severe under the Empire, and flower pots were introduced in windows, and even the houses of the poor in Rome had little gardens in front for ornamental plants—equivalent to our window gardens—while the villas had highly decorated gardens attached to them, and there were parks and pleasure grounds in the heart of the city. The favourite garden trees were the Pine, for its refreshing odour; the Bay, for its beauty and fame; and the Box, for its shade. Trees were regarded as the temples of the gods. "The simple peasants, savouring of antiquity, do still," says Pliny, "consecrate to one god or another the fairest trees, and we ourselves worship the same gods in the silent groves with not less devotion than we adore their images of gold and ivory in our stately temples."

We proceed to notice a few of the plants in their passage westwards in different ages, without attempting to fix the exact date of their arrival at different ages, or to settle disputed dates. Caesar found in Britain the Apple, Hazel, Elder, Bullace, Sloe, Raspberry, and Blackberry; and his successors left us the Vine, Cherry, Peach, Pear, Mulberry, Fig, Damson, Medlar, Walnut, &c. In all probability, some of the trees cultivated in the gardens of Roman generals, or governors, in Britain, were afterwards lost, as would necessarily be the case with neglected plants, especially in the case of those whose seeds do not ripen in our climate; and they were re-introduced in the monastic age. The Sweet Chestnut, for example, had long passed from Sardis to Tarentum and Naples, where it was cultivated with much care and success, and the Romans would bring such a rapid-growing and favourite tree to ornament their English villas, as surely as they brought the Rose herself; and the disputants who denied as the Chestnut until late in the Middle Ages, are refuted by common sense as well as by Giraldus Cambrensis, who, writing in the twelfth century of the trees of Britain which Ireland wanted, mentioned the Chestnut and the Beech. As to the Sorbus, or true Service tree, there is no dispute; and it is singular that one of the few habitats where it is still found wild in England is in Wyre Forest, in Worcestershire, near the remains of a Roman villa, and of the orchard attached, in which, perhaps, it was first planted. The same orchard may have ripened the first of many of our fruits, sheltered, perhaps, by the first nursery of the narrow-leaved, or "English Elm;" and in the garden near may have been planted the first Rosemary and Thyme that had lately blossomed on Mount Hymettus. The Plane passed from Asia to Sicily, thence into Italy, and, as Pliny informs us, had reached the northern shores of Gaul before the year A.D. 79. The Peach was common in Gaul in the time of Agricola, so that these, with the Box and Poplar, followed the Cherry, which came here within five years of the settlement of the Romans. The Apple, though not perhaps native, preceded them by some German route, and had given a name to the British Avalonia, afterwards called Glastonbury; but it profited by the rural industry of the Romans, and soon spread over the whole island to Ultima Thule. Early among the fruits came the Walnut, called Juglans, Jovis glans, in remembrance of that golden age when the gods ate Walnuts and men lived on Acorns. We pause with the wandering fruits and flowers on the shores of the Mediterranean, to note down the names of a few that the Romans acquired, or the Britanni gained from their imperial visitors. It is time to notice the sudden cessation of migrations when the Empire and its gardens in Rome and Britain were trampled under foot by the Northmen. The Moors were more civilised conquerors than the wandering nations of the north, and they brought to Western Europe the Persian forage plant, *Lucerna* (*Medicago sativa*), still called in Spain by the Moorish

name *Al-fafa*, and the Sugar Cane, which had then only the Atlantic between it and the West Indies and the future sugar States of America. Some of the flowers which Spain gained from Arabia may have been passed into Holland by Charlemagne, who lived on the banks of the Rhine in a country house with a large garden; but it is not easy to get a glimpse at the horticulture of that dark age, and Holland was trodden down afterwards by such ravagers as the "Wild Boar of Ardenues," who must have rooted up many of Charlemagne's flower bulbs; and it was not until after the fall of the Eastern Roman Empire, A.D. 1453, that the Ranunculus, Anemone, Tulip, Hyacinth, and Narcissus—which were all Oriental before they became "Dutch bulbs"—found a permanent home in Holland, having first arrived in the bales of Dutch traffickers from Persia, by way of Constantinople.

Introduction of Forest Trees and Shrubs into England.

England next began to furnish her gardens from abroad. They had been sadly trampled under foot, and their ruin was never more complete than during the comparatively recent Wars of the Roses. In earlier days every abbey and religious house had a carefully cultivated garden, and those south of Trent had their Vineyards; and even crusading barons, with some contempt for rural labour, had not visited the coasts of the Mediterranean without gaining some hints for their English gardens. Quit-rents were frequently paid in fruits and flowers. In 1205 Robert de Evermere held his lordship of Redham, in Norfolk, in petty serjeanty, by yearly payment into the Exchequer of 200 Pearmain and 4 hogsheads of wine made of Pearmain (perry). The Rose must have been extensively cultivated when vassals were bound to deliver them to their lords by the bushel. But the Wars of the Roses trampled down the Rose beds, and in the course of time a single Rose came to represent the bushel of Roses, just as the single Peppercorn did the pound of pepper, when a "Peppercorn rent" superseded the original bargain. A new era of gardening began after the reign of Henry VII., when the Middle Ages came to a close, and the great barons and proprietors were replaced by the English country gentlemen. Hops were introduced in 1523; orchards, for the sale of fruit, were planted in "the garden of England" by Henry the Eighth's fruiterer; great houses were built and surrounded with planted grounds, and their owners began to look abroad for shrubs and trees of ornament. Henry VIII. built Nonsuch, and encompassed it with parks full of deer, and laid out gardens and groves and walks embowered by trees, doubtless including the famous Pippin of that name, so that—

This, which no equal has in art or fame,
Britons, deservedly, do None-such name.

Hampton Court eclipsed even "Nonesuch;" Hatfield, Holland House, Theobalds, and Greenwich followed, with others too numerous to mention. Eighty-four foreign trees and shrubs were used at this time in the decoration of English gardens, and in the next reign a host of planters were seeking for new material. The Tamarisk was among the productions at Fulham—still famous for its historic trees—where Bishop Grindal so surrounded his palace with foreign and native foliage that his guest, Queen Elizabeth, declared she could not see from her chamber window for trees. Cecil's house at Wimbledon was also famous for trees and shrubs and Raleigh's at Sherborne for woods. Burleigh had the best collection of plants in the kingdom at his mansion in the Strand; and Gerrard, author of the "Herbal," who lived at the Physic Garden in Holborn, superintended the Lord Treasurer's grounds. Bacon, too, now formed his plantations at Gresham, and wrote his essay on "Gardens." Amongst the new plants the "noble Laurel," or Sweet Bay (*Laurus nobilis*), sacred to Apollo, and emblem of victory, paid its second visit to England; as did the Portugal Laurel, which was introduced into the Oxford Botanic Garden in 1648, and the common Laurel, which reached the West from the shores of the Black Sea by an unusual route. It came first to Constantinople, and was then sent by the German Ambassador in 1576, to Clusius, keeper of the Botanic Garden at Vienna. The "Plum of Trebisond," as the Laurel was called, arrived with a Horse Chestnut and other rare trees and shrubs, having narrowly escaped the dangers of winter weather and rough treatment. It was placed by Clusius in a stove, when nearly dead, and was saved and propagated and distributed amongst the friends of the botanist. We, however, obtained "this rare tree," as Evelyn called it, from Italy, and our oldest Laurel was brought from Civita Vecchia, in 1614, by the Countess of Arundel, who planted it at Wardour Castle. "The Fig of Spain," as ancient Pistol and others have erroneously called it, was re-introduced by Cardinal Pole, who planted it against the wall of Lambeth Palace when he returned from Rome, Archbishop of Canterbury, after the death of Henry VIII. Later still—a century ago—Pocock, the Eastern traveller, and predecessor of Dr. Pusey in the Regius Professorship of Divinity, is said to have brought back a

Fig plant from Syria, and to have planted one, at least, of the venerable Fig trees which are among the glories of Christ Church, Oxford.

The First Market Gardens.

Amongst the most useful plants, which had been long driven from our gardens and were now about to return, were the kitchen vegetables. Henry the Eighth's table was supplied pretty liberally from the Royal gardens at Richmond and Greenwich, where Melons and Cucumbers were now forced as they had been at Rome 1,500 years previously, and Grapes, Peaches, and Apricots were trained to the 14-foot wall at Nonsuch. The revival of gardening had commenced, but although Tasser, in his "Five Hundred Points of Good Husbandry," mentions 150 fruits and plants cultivated in gardens, including all the common vegetables, "kitchen garden wares" continued to be imported from Holland, and fruits from France, until market gardens were established about the year 1600; "before which," says Fuller, "we fetched most of our Cherries from Holland, Apples from France, and hardly had a mess of rath-ripe Peas but from Holland, which were dainties for ladies, they came so far and cost so dear. Since, gardening hath crept out of Holland to Sandwich in Kent, and thence to Surrey, where, though they have given £6 an acre and upwards, they have made the rent, lived comfortable, and set many people to work." A new continent gave us at this time the Potato, and sent two great travellers, the Tobacco plant and Maize, to grow in future side by side in many countries of the Old World; while the eastern hemisphere conferred on the west its Apples, Pears, and Peaches, with its Bread-fruit and bread-corns—Wheat, Rice, and Millet. The Mango came later still to the far West, and the delicious "No. 11," and the "No. 132," so justly prized in Jamaica, retain as their names the numbers with which the specimens were labelled in the collection captured in a French Indian man by Rodney, and taken by him into Kingston Harbour. America had few indigenous fruits adapted to our gardens. But let us be grateful for the Pine. Evelyn, who "first taught gardening to speak proper English," was present at the Banqueting House at Whitehall when his Majesty's gardener, on bended knee, presented Charles II. with the famous Queen Pine from Barbadoes, and as Pines and forced fruits soon began to be grown for sale by the London gardeners, we may conclude that English gardens henceforth supplied English tables without foreign help. Evelyn describes his brother's house at Watton as among the most magnificent examples of ornament of wood and water, "till the late universal luxury of the whole nation since abounding in such expenses." Among the recent introductions which were planted at Watton, when Evelyn himself inherited it, were Cedars, Larches, Silver or Spanish Firs, and Walnuts. "Sylva" was published in 1661; and, as hospitable hearths and timbered houses had made inroads on the forests, planting for utility soon became popular. "Sylva" recommended indigenous trees for profit; nevertheless, new trees and shrubs continued to arrive. Tradescant, a Dutchman, and one of Charles the Second's gardeners, travelled over Europe to collect plants, and visited Barbary, Greece, Egypt, &c., and his son went to Virginia on a similar errand. Among the new trees that the good bishop, Dr. Compton, was able to plant in his garden at Fulham, were the Tulip tree, Magnolia, deciduous Cypress (Swamp Cedar), Western Plane, and some other North Americans, and the Cedar of Lebanon in 1683.

Early Botanic Gardens.

Among the public and private botanic gardens which became rich in plants by the end of the seventeenth century, were the Chelsea Botanic Garden, presented afterwards, by Sir Hans Sloane, to the Company of Apothecaries, and claiming two Cedars of Lebanon, planted in the first year of their introduction; Ray's garden in Essex, Dr. Sherard's at Eltham, Dr. Uvedale's at Enfield, and that of the Duchess of Beaufort at Badminton. Before mentioning the exotic Oaks which, with a single exception, arrived at one or other of these gardens after Sylva Evelyn's time, we must refer to the two British species, *Quercus pedunculata*, or the common Oak, and *Q. sessiliflora*, the sessile fruited Oak, the grandest of a noble family in form and bulk, the longest lived, and the strongest timbered. The American cousins of our Oaks are more distinguished for their foliage and its rich autumnal tints, than for the durability of their timber; and their proper place is in the pleasure garden rather than in the wood. Three characteristic Oaks from the Mediterranean—the cradle of our exotic trees—are the *Quercus cerris*, the Turkey or mossy-cupped Oak, with its deeply-lobed leaves and fine tufted foliage; *Q. ilex*, the evergreen or Holm Oak, which has ornamented English shrubberies since Queen Elizabeth came to the throne, and has left its mark in King James's Authorised version of the Bible, A.D. 1611 (Susanna, 58); and *Q. suber*, the Cork tree, another evergreen species which grows in Kensington Gardens, and many other places, and needs no label, being sufficiently marked by its wrapper, or rind, of cork. Besides our long

list of foreign acquisitions, numerous hybrids have appeared, subsequently, on the scene of English gardening and arboriculture; the sub-evergreens known as the Fulham Oak and the Lacombe or Exeter Oak having been among the first offspring of our naturalised trees. The first is a round-headed; the second a pyramidal rough-barked tree, rapid of growth, like the Turkey Oak, and bearing a general resemblance to it and to its other parent, the Cork tree.

Early Tree Planters.

In the eighteenth century the number of patrons and planters of trees greatly increased. The Duke of Argyle stocked his garden at Whifton, and received, according to *Macmillan's Magazine*, from Horace Walpole the honourable sobriquet of "treemonger." At the same period, the first great planter of another dual house began to clothe the hill and mountain tops at Blair Athol and Dunkeld with a timber tree which Pliny had admired for its durable and incombustible nature, and which was used for the Forum of Augustus, and for many of the buildings and bridges of Rome. The Larch had been introduced into England a hundred years before it arrived at Dunkeld with some Orange trees in 1727; but it had not been planted as a timber tree till it found its way from the hothouse to far colder situations on the Duke of Athol's estate, covering at length more than 10,000 acres, and yielding an immense revenue.

MORRIS'S CHARTOMETER.

WE have in a former number (see p. 382) alluded to this convenient little instrument; and, after having tested its accuracy in several ways, we have to confirm our previously-expressed opinion, that it

Morris's Chartometer.

will prove exceedingly useful in measuring distances from place to place on maps, by circuitous roads or rivers. With all such maps as have been laid down to regular scales—such as one inch, half an inch a quarter of an inch, or an eighth of an inch to a mile—the instrument, with its present set of moveable paper dials, is all that can be desired; and we should recommend Mr. Morris to give a few additional dials to suit maps in which a fractional portion of an inch to a mile has been adopted; such, for instance, as the atlases of the Society for the Diffusion of Useful Knowledge, and others that might be named. H. N. II.

Green Food for the Polar Expedition.—Mr. Maw, of Brosley gives in a contemporary a useful hint for arctic voyagers. A few hundredweight of Mustard and Cress seed would afford (he says) the means of providing the Polar Expedition with an unfailing crop of green salad. Green Mustard, an effective anti-scorbutic, could be raised on board ship without a particle of soil by thinly sprinkling the seed on a piece of wet flannel or on the surface of a layer of moist ashes.

THE KITCHEN GARDEN.

DREER'S IMPROVED LIMA BEAN.

LIMA BEANS are a rather troublesome vegetable to prepare for the table, on account of the difficulty of shelling them; their pods do not open so readily as those of other varieties, and the operation requires strength of thumb nails as well as patience. In the ordinary Lima there is a great waste of pod; the Beans are set wide apart, and the pod is often so constricted that the halves touch between the Beans. A large pod will frequently have but two, or at most, three Beans, but this can be improved by selecting for seed only those pods which have four (or more if possible) Beans in them. The Lima is a distinct species (*Phaseolus lunatus*) from the common bush and pole Beans (*P. vulgaris*), and shows very little disposition to depart from its natural condition, or, as the gardeners phrase it, it will not "break" readily into varieties. Some years ago one of our western friends made many experiments, with a view to producing a low-growing or bush Lima, but when we last heard, he had not succeeded in overcoming the disposition to go to the top of a tall pole. A few years ago Mr. Henry A. Dreer showed us some Limas which he considered a great improvement upon the ordinary kind, and this year we received from his son a basketful of the same Beans for trial. We learned that this variety is the result of a careful selection carried on for some twenty years. In these Beans the pods are not only full, with no spaces between, but are as full as they can stick, the seeds so crowding one another that the ends of the central Beans are square; the Bean is also much thicker than the ordinary kinds. A vine of this description bearing the same number of pods as one of the ordinary sort, would, we should judge, yield nearly, if not twice, as much in shelled Beans. It is stated that this variety is much more productive than the common species, yielding as it does many more pods to the pole. The pod being so completely filled, the shelling becomes an easy matter, and the Beans when cooked are much superior to the ordinary ones, as the amount of skin is much smaller in proportion to the enclosed nutriment. We regard the improving of this Bean as one of the most important of the recent contributions to horticulture. We take quite as much, if not more, interest in a new variety, or the improvement of an old variety, of garden vegetables, as we do in those among fruits and flowers. And he who makes three Lima Beans grow where there were only two before, is entitled to quite as much credit as one who produces a Colens with a new stripe in its leaf, or a Strawberry a trifle larger than any other, and horticultural societies should offer equally large premiums for improvements in the one class as in the others. [The above, from the *American Agriculturist*, reminds us of a delicately-flavoured and distinct species of edible Bean, which we have never seen in this country. It may not be possible to cultivate it successfully in the open air, but in large forcing gardens there are opportunities for testing its merits. The treatment usually given to Tomatoes in this country might be tried.]

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Keeping Celery in Cold Countries.—A correspondent of the *German Town Telegraph* says:—"A friend of mine has kept his Celery through the winter now for several years by setting it in spring water about an inch in depth; and, kept thus, it continues to grow and send up fresh leaves, so that he has cut nicely blanched tender tops two or three times in a winter. My trouble with the trench system has been meadow mice, which appear to be quite as fond of the plant as I am, and make sad havoc with it. Otherwise, it was the best way to keep it which I had an opportunity of trying."

Forcing Vegetable Marrows.—I will be almost completely run out of vegetables by the end of April, and as my employers are very fond of Vegetable Marrows, do you think I could have some fit for table by the beginning of May? I have some good brick-built Melon pits of the ordinary size, and plenty of fermenting material at command, both stable dung and Oak leaves, but no other heat. Under such circumstances, can I force Vegetable Marrows to come in by the time mentioned, or what other vegetable might I have fit for table at that season? Asparagus will not grow in our gardens under any circumstances, though I do not know why. The roots seem to rot away the second or third year after planting, leaving no trace of them behind. Perhaps some of your correspondents will kindly assist me in this matter.—T. S., *Limerick*.

Great Yield of Rhubarb.—A market gardener, near Providence, sold in that market last spring and summer nine tons of Myatt's Linnaeus Rhubarb from a quarter of an acre of land. Owing to very sharp competition he only received 45 a ton for it, or about a half-penny per pound. This is £45 worth of produce from a quarter of an acre, or £180 per acre. If it had not been for competition, and the Rhubarb had been sold at former season's prices, he would have received at the rate of £360 an acre for this crop. This, the *Agriculturist* says, is by no means an unparalleled return for such crops. It is a result of a very liberal use of manure and labour, and of adapting crops to the wants of the market. A farmer uses £10 worth of manure and thinks he is very extravagant. A market gardener uses £40 worth on rich land, and regrets that he had not put on more.

BIRDS FREQUENTING THE BOTANICAL GARDENS, REGENT'S PARK.

As reference has lately been made to the various kinds of birds which are to be met with in, or close to, London, I think it may prove interesting to some of your readers to be furnished with the result of my own personal observations of the birds which have been seen in the grounds of the Botanical Gardens, Regent's Park. I have had the pleasure, from time to time, during the last few years, of sending you accounts of particular birds which I have seen there; but I have not hitherto furnished you with a complete list of the species met with. The following may be relied on:

House Sparrow	Rook	Chiff-chaff
Tree Sparrow	Jackdaw	Willow Wren
Hedge Sparrow	Greenfinch	Golden Warbler
Robin	Yellowhammer	Reed Warbler
Chaffinch	Linnet	Blackcap
Larger Tit	Goldfinch	Whitethroat
Long-tailed Tit	Lark	Nightingale
Cole Tit	Pipit	Fly-catcher
Blue Tit	Wagtail	Cuckoo
Song Thrush	Kingfisher	Fieldfare
Mistletoe Thrush	Redpoll	Redwing
Blackbird	Siskin	Moorhen.
Starling	Tree Creeper	

From this list it will be seen what a great variety of birds congregate in one small place not far from the centre of this metropolis. I am certain I might add to their number; but, as the value of such observations depends upon their exactness, I have taken nothing for granted unless it agrees with my own individual testimony. For instance, I was informed, on most excellent authority, that a brace of partridges were seen there in the last spring; I have been informed, also, that a bullfinch was captured there some time ago. However, I did not see either of these birds although I fully believe in their having been seen there. I have also seen two or three birds which I could not make out to my satisfaction, and, therefore, do not include them in my list. It will be seen that not only does the list include those birds which are most familiar to us, and usually take up their abode with us, but a considerable number of migratory birds which traverse large tracts of land and sea, and, without doubt, repeat their visits to the identical spots where they had taken up their abode before, and where they have reared their young. The non-migratory birds are very numerous, and I am sure they have increased much since the Bird Act was passed. Their increase would be greater if we could manage to secure the nests in the early spring against boys and cats. I dare say it will be a matter of astonishment to some to find such birds as the linnet, redpoll, goldfinch, and siskin—the last three are rare visitors—but I have often seen linnets, and two summers ago a pair nested there. I noticed them in a particular part of the garden for some time, and felt sure there was a nest, but could not discover it. In due course my suspicions were verified in seeing a family of six birds flying about; and, when autumn came and stripped the shrubs of their leaves, I found the nest at the very spot where I suspected the birds would build it. Of the migratory birds, the willow warbler is most frequently seen; next perhaps the reed warbler, whose curious chattering most surely betokens the situation of its nest, which in these gardens is generally built in a lilac tree. I have seen as many as five or six of these nests here in one summer. We generally get two or three pairs of blackcaps; I have, however, only on two occasions met with a nest of these birds. The chiff-chaff always visits us, but not in numbers. I noticed one curious circumstance in reference to this bird which is worth relating. In March, 1872, I heard this bird one fine morning; two or three days afterwards heavy snow fell, and the morning after the fall, whilst it was still cold, I saw a chiff-chaff flying about in the conservatory. It remained there for a week, enlivening the place with its merry notes and doing an immense deal of service by devouring the insects which infest the plants. In about a week the weather became milder, and the little fellow took his departure from the place where he was so warmly housed and so plentifully supplied with food. I have both heard and seen the nightingale every spring for the last five years, with the exception of the year 1872, and then I was told it had been heard, but I did not hear it myself. With regard to one bird which is mentioned in this list, viz., the long-tailed titmouse, I never expected to see it, nor have I seen one in the gardens until this autumn, when, curiously enough, I saw a flock of nearly a dozen flying together rapidly from tree to tree; they were evidently *in transitu*. When I was a boy at Harrow, nearly forty years ago, I often used to come across their beautiful nests; but I believe this bird is comparatively rare near London now.—HENRY SMITH, 82, Wimpole Street, in Field. [There are two or three other birds which we should have expected to see mentioned as observed from time to time in the Botanical Gardens, such as the swallow and martin, and the tiny golden-crested wren,

which often visits London gardens in winter, in company with titmice of different species. Perhaps our correspondent has accidentally overlooked these.]

THE PEZIZA CLASS OF FUNGI.

THE *Pezizas* form an immense class. Fully 100 have been described as natives of our island, some few being said to be esculent. Their form, in general, is cup-shaped, the cup, in some instances, being beautifully coloured, and holding the germs of reproduction, which are thrown off like a thin wreath of vapour when the sun is shining warmly on the Fungus. Indeed, the *Peziza* cups are, as a whole, very sensitive to light, and often remain closed and spenia-like when growing in caves or dark recesses. Various, indeed, are their places of growth; some are seen on fallen branches, some on dead leaves, some on the ground among the grassy turf, and some, again, are denizens of the hot-bed. I shall describe a few of the more conspicuous that occur with us around the Lodge:—*Peziza coccinea*, a true winter beauty, is abundant with us on mossy banks among Hazels. It seems, indeed, to select Hazel-sticks as its favourite place of growth. Nothing can surpass the rich vermilion of this fairy cup; and when the stick on which it grows, and which is hidden from sight, is covered over with the dark green *Hypnum* Moss, it looks like a flower rather than a Fungus. These cups may be kept for a long time in beauty by simply unearthing the sticks on which they have fixed themselves, and occasionally moistening them with rain-water. Another species, almost as beautiful in colour, but not so symmetrical in form, is the *Peziza ruticans*, that grows among the sward of upland pastures. I met with it in plenty in October, on the Ormes Head, Llandudno, growing among the turf of the carboniferous limestone of the headland. This species throws off large jets of sporidia in the sunshine. Its colour is orange-red; and it surpasses the *Peziza coccinea* in size of cup, though it is apt to be distorted in growth. *Peziza vesiculosa* has its home on old dunghills, and attains to a large size. The exterior of the cup, which is pale amber, is marked with pustules which are imbedded in scurf; hence the name. It is difficult to obtain a perfect cup, as the gregarious nature of this *Peziza* materially interferes with the regularity of the cups. I am always pleased to see a pretty little brown *Peziza* cup in the early spring, as it tells of coming flowers again. It rises among the turf from a black tuber some 2 or 3 inches below the surface, and hence it is called *P. tuberosa*. The cup is of a rich brown, and beautiful in form. The Shell *Peziza* (*Peziza cochleata*) also appears in the spring. It is of a dark amber, sessile, and cespitose. I find it under hedge-banks in grassy places, where it attains to goodly proportions. The last I shall mention is the Orange *Peziza* (*P. aurantia*), growing chiefly on the ground in woods. The cup is large, and bright orange externally, frosted with sparkling granules. I have met with it under Fir trees.

PETER INCHEALD.

Haringham Lodge, York.

A Hint for intending Emigrants.—According to the report of Gen. Brisson, sent to Western Nebraska by Gen. Ord to ascertain the true state of things among the settlers there, the inhabitants of eight counties in Western Nebraska "have literally nothing in the shape of fuel, clothing, or food to carry them through the coming winter." He found the people without meat, living on Pumpkins, Squashes, and black shrivelled corn bread, and, when he left, not an average of ten days' supplies remained. "One-third of the people are in a state of almost nakedness." The same authority says, "Ten thousand people in this State will need aid sufficient to keep them from starvation and being frozen to death this winter. Hundreds of people are naked and on the verge of starvation, and without means to leave the State."

Preserving Wooden Labels.—After the wooden labels are made, soak them in a strong solution of sulphate of iron. Let them dry, and then place them in lime-water, giving time for the lime-water to permeate the wood thoroughly. Insoluble sulphate of lime will be formed throughout the pores of the wood, which will prevent the absorption of water and consequent rotting. Twine used for tying up plants may be similarly preserved.

OBITUARY.

We have to announce, with regret, the death of Mr. Daniel Nash, the head of the old-established house of Minier, Nash, & Nash, seedsmen in the Strand. The event happened last Saturday, after a brief illness. Mr. Nash had been ailing for some time; but it was only last week that serious symptoms set in. He may be said to have been the father of the London seed trade, and has for nearly half a century occupied a position in which he was held in the highest respect.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 2ND.

THIS, the last floral meeting this season, was not so well supported as usual, it being too cold to bring out Orchids or even delicate stove plants. It was announced, as a new feature for the forthcoming season, that popular and scientific evening meetings would be held during the months of January, February, and March, to which fellows and their friends will be admitted. Prof. Dyer stated, in reference to the Royal Agricultural Society's attempts to check the Potato disease, that none of the reputed disease-proof varieties were found to resist that malady better than ordinary kinds. He exhibited wax models of *Stephanotis* fruit, and remarked that the sweet-scented tubular flowers of this favourite *Asclepiad* were perfect traps for insects whose presence was necessary to secure fertilisation in the absence of manual manipulation. Mr. E. G. Wrigley, of Broad Oaks, Bury, Lancashire, sent, through Messrs. Veitch & Sons, a new white-flowered crimson-blotched *Odontoglossum*, named *O. maxillare*. In habit it resembles *O. cordatum*, but the flowers are far more beautiful and distinct as regards colour. It bore a three-flowered spike, and well deserves general culture as a decided acquisition to an already beautiful genus. Mr. Brush sent six pots of a new double Neapolitan Violet, named *Lady Hume Campbell*. It has rather larger and deeper tinted flowers than the common form, and well deserves attention. Mr. Charles Green, of Reigate, sent a young plant of *Physianthus albus variegatus*, with oblong undulate yellow-margined foliage. In general appearance it resembles the variegated form of *Cobaea scandens*. Messrs. Standish & Co., of Aescot, contributed about a dozen dwarf plants of *Poinsettia pulcherrima*, with well-developed heads of vivid scarlet bracts. These varied in height from 15 to 18 inches, and when dwarf, as these were, are well adapted for all kinds of indoor decoration. Dwarf *Poinsettias* may be readily obtained by cutting the tops off tall and straggling plants just after the bloom buds are formed, and inserting them at once in a genial bottom-heated propagating case, in which they root nearly as readily as *Gardenias*. Mr. Smith, of Ealing Nurseries, sent six or seven dozen of well-grown profusely-flowered *Cyclamens*, among which we noticed some fine and distinct forms. The *Cyclamen* is now found to be one of the freest and most manageable of all winter-flowering plants, and its odorous flowers are unsurpassed for bouquets, button-holes, and, indeed, for all kinds of floral decorations. Messrs. E. G. Henderson & Son sent a beautiful and well-flowered group of perpetual-flowering or tree *Carnations*, the deliciously perfumed flowers of which are so useful at this season. The same exhibitors also sent a new *Dracena* named *D. Duffii*. It is robust and compact in habit, having broad foliage, coloured as in *D. terminalis*. It promises to become a favourite with all lovers of fine-foliaged plants for exhibition. Messrs. Veitch & Sons sent specimens of their new self-protecting *Broccoli*, to which we alluded in favourable terms a week or two ago. Mr. E. Bennett, of Hatfield, sent two brace of Sutton's Improved Syon House Cucumber, in excellent condition. A fine collection of *Celery* was furnished by Mr. Barron, from the Society's garden, at Chiswick. Mr. Woodbridge, of Syon, brought a small dish of the plump richly-flavoured fruit of *Musa Champua*, which is said to be one of the finest of all the cultivated varieties. This being the last meeting of the year Dr. Smee's prizes of £5 each for the best dish of fruit and the best dish of vegetables staged before the Fruit Committee during the season, were awarded to Mr. Pearson, for his new seedling Grape, Golden Queen, and to Messrs. Vilmorin, of Paris, for their Seville long-pod Bean.

MANCHESTER GREAT FLOWER AND FRUIT SHOW

THE hall in which this show was held, in the Pomona Gardens, has an area of no less than 45,000 square feet, and is divided by pillars into what may be called a nave and four aisles, the length of which is 72 yards, while the breadth varies from 9 to 18 yards. It was fitted up for the exhibition with suitable stages, all of which were well-covered with plants and flowers, while in the centre were tables loaded with choice fruit. When we say that the schedule contained fifty-eight classes, that there were over 100 exhibitors, and more than 2,000 entries, it will be evident that the number of exhibits was great. These were backed up by the famous Pear growers of the Channel Islands. The Rev. T. C. Brehaut, of Guernsey, showed six Pears which were only a few ounces under 20 lb. Prominent among exhibitors of *Chrysanthemums* were Messrs. Grant, Copeland, Corfield, Lister, Norrie, and Rhodes; while among those who furnished miscellaneous collections of plants, we observed the names of Messrs. Liscombe, Pince & Co., Shuttleworth, Cole & Sons, Williams, Yates, Dickson & Co., and many others. The principal prizes for fruit were awarded to Messrs. Cypher, Turner, Wilkes, Hodgkins, Upjohn, Coleman, Roberts, Stevenson, Wildsmith, Jamieson, Fairbairn, Thomas, Rylance, Ross, Robinson, Gardener, and others. Some fine *Hollies* and *Conifers* (shown from the Exeter Nurseries) had a fine effect in the large hall, which was literally crowded with garden produce of every description. Silver medals for the most meritorious plants in the exhibition were awarded to Mr. Shuttleworth for *Gleichenia rupestris*, and to Messrs. Cole & Sons for *Cocos Weddelliana*, both fine specimens of their respective kinds. Of Roman *Hyacinths* some beautiful examples were shown by Mr. Collins, gardener to J. Todd, Esq.; pyramidal *Cockscombs* by Mr. Yates, and hanging baskets by Messrs. Dick Radclyffe & Co. *Cyclamens*, *Orchids*, *Heaths*, and other plants, together with bouquets and cut flowers, were abundant.

THE GARDEN.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE NEGLECT OF PLANTING IN THE PARKS.

YEAR by year the fine old trees of Hyde Park and Kensington Gardens are getting sadly thinned. Some fall in the ripeness of age by the ravages of a sudden windstorm; some, having reached a period of natural decay, crumble, as it were, branch by branch, till the unsightly remnants of their trunks are no longer allowed to cumber the ground—removed as useless lumber; others, again, to suit some supposed improvement in the direction of a path or the opening of a vista, are ruthlessly cut down in their prime. These, and many other analogous causes, have reduced the number of full-grown trees to an unsatisfactory extent, and it becomes a serious question how these gaps are to be filled. A good deal of useful planting took place some forty years ago, and the trees then planted are beginning to do good service in replacing the fine old Elms of the parks which have disappeared. These new trees stand in groups of five, eight, or ten, in tolerably well-selected situations; and, in some cases, two or three members of these groups evince such robustness and capacity for rapid growth, that their inferior companions might advantageously be removed to give them a chance of becoming bi-centenarian giants, fit to replace those of their predecessors that have fallen or been destroyed. It is to be feared, however, that, with every advantage, the vicinity and approximation of smoke-vomiting chimneys will prevent their ever attaining to the noble dimensions of their ancestors. However, with careful treatment, such as watering during summer droughts, top dressing the roots with rotten manure during the winter, and judicious pruning, to strengthen the lateral branches and impart vigour to the main stem, much may be done, in spite of the smoke plague and other difficulties. The plantations of the Regent's Park have had some twenty years longer for the development of their growth than those in Hyde Park; and are, consequently, more advanced, and their greater distance from the heart of London has also been of advantage to them. The avenue of Horse Chestnuts and Elms in this park is, indeed, in a most thriving condition; and many of the trees, from their apparent robustness, are probably destined to make big wood, notwithstanding the encroachments of "brick and mortar," and other disadvantages. But, notwithstanding all the improvements of the last half century, much still remains to be done in order to make the cultivation of young trees counterbalance the decay or destruction of the old ones. It is necessary that a systematic course of planting should be annually in operation, both in late autumn and early spring. Economy may be pleaded as a reason for not pursuing a regular system of planting, but let it be borne in mind that thousands are now lavished every season on a display of bedding plants, the cost of which has to be renewed every year; while a fine young tree, if well selected and well planted, is an investment for a century. The bedding system, though attractive to many, has been somewhat overdone. Acres of green turf (which, after all, forms the most attractive feature of a park), have been displaced to make room for the display of masses of Geraniums and other bedding plants during their comparatively brief season of florescence, whilst the rest of the year their empty beds remain bare unsightly patches. Surely, then, it would be advisable to curtail the outlay yearly expended on bedding plants, and devote the surplus to the general improvement of the parks, and especially to the recovery, by systematic planting, of the losses incurred by the yearly perishing of old trees. In some respects, the gaps caused by time among the trees of the older London parks are scarcely to be regretted, inasmuch as a number of fine kinds have been introduced since the period during which the parks were originally planted, which are calculated to display much more variety and beauty of foliage than was at the command of planters a century ago. With a view to the extension of such judicious innovations, a certain section of Hyde Park

and Kensington Gardens should be carefully examined every year; and worthless trees and shrubs removed to make room for newer and better kinds. In this way, in the course of eight or ten years, the tree vegetation of the Park and gardens would be thoroughly renovated, and the plantations placed in a fair way to be bequeathed to our successors in a promising state. Pending such changes in our parks, there is Primrose Hill to begin upon. It is at present a treeless mound, like an inverted green wash-hand basin, and calls aloud for the landscape gardener to redeem it from absolute ugliness—a redemption easily achieved if the right means are adopted. We have only to turn to the Botanical Gardens in the Regent's Park to see what can be done with a far less extent of ground. Primrose Hill affords excellent opportunities for skilful planting; and, yet, this promising ground is allowed to remain fallow year after year. H.

TREE PEONIES.

(P. ARBOREA.)

THIS beautiful plant, although introduced long ago, is not yet very plentiful in English gardens. It is, however, abundant, even in small gardens, throughout the Netherlands, Belgium, France, and Germany. On this side of the Channel there have been, and are still, numbers of amateurs who make its culture a speciality, and who endeavour to raise from it new varieties; in fact, it is a plant which deserves to be more extensively cultivated than it is, especially now-a-days when we are doing away with band and ribbon systems of decoration, and are reverting to more natural modes of plant culture. The tree Peony is quite hardy, and, when properly planted, requires little more care. It is especially well suited for forming single specimens on lawns, and if, during the winter months, its appearance is against it, this drawback is amply compensated for in summer, when it becomes covered with fine foliage and gorgeous blossoms. When, too, it breaks into growth in spring, its young leaves assume every shade of colour, from violet-crimson to green. Until the second half of this century we knew but of such sorts as had white, rose, salmon, and lilac-coloured flowers; and we must acknowledge that we are greatly indebted to Mr. Fortune for the introduction of his Chinese varieties, most of which have scarlet, violet, and magenta-coloured flowers. Von Siebold, too, introduced a number of Japanese varieties, which, however, form a different race, and are mostly single or semi-double. Tree Peonies are not very particular as to soil or position; I have seen them in nearly pure sand, flourishing as well as in a strong loam. They, however, prefer a good strong soil, and where the soil is too sandy it should be made a little better suited for them by adding decomposed manure and loam; or, where it is too clayey it should be made lighter by means of the addition of manure, sand, and similar materials. Mountans are gross feeders, and amply repay for occasional top-dressings of half-decomposed cow-dung. Of the scarcer and best varieties nurserymen generally send out one or two-year old plants, grafted on the roots of *Pæonia edulis*. After a proper place has been selected in which to plant them, dig out a pit 1½ feet deep and 2 feet in diameter; put in a few inches of half-decomposed cow-dung, and well mix it with the soil. The plants should be put in so that the graft may be buried a few inches under the ground, where it will, in time, throw out roots of its own. They do not flower well until the third year after planting, but, after that, they produce blossoms in profusion. Some of the more strikingly beautiful among them, such as Gloria Belgarum, Elizabeth, and Souvenir de Gand are well worth being put under glass—that is, they should have a sash or two put over them in spring to save them from late frosts and rainy weather. Of course plenty of air must be admitted, but, so treated, the flowers are gainers in an astonishing degree, both in size and colour. The parent plant of Gloria Belgarum was kept by its raiser, Mr. Goethals, at Ghent, in a house-yard, under a little glass-house, and when I saw it in 1854 it measured about 5 feet in diameter, and was bearing some forty flowers of a bright salmon-rose colour, each bloom measuring about 8 inches across. It was indeed a sight worth travelling miles to see.

MAX. LEICHTLIN.

NOTES OF THE WEEK.

— IN Mr. E. W. Cooke's garden at Glen Andred, in Sussex, the Tea plants, *Thea viridis* and *Bohea*, have stood out in a sheltered nook, without protection, six winters. *Thea Bohea* is said to be still in beautiful and abundant blossom.

— SOME fine Yams and Sweet Potatoes, have been brought into Covent Garden during the past few weeks. In appearance they resemble huge red Potatoes, and when roasted are said to be excellent in flavour.

— It has been resolved, on the recommendation of the Parks, Commons, and Open Spaces Committee, that additional planting and fencing be carried out on Stoke Newington Common, at an estimated cost of £100.

— CHRISTMAS decorations in the form of wreaths and other floral devices, already form a prominent feature in Covent Garden Market. In the construction of these berried Holly, silvery Immortelles, capsules of the Gladwin, and bleached Grasses are used with excellent effect.

— MANY of our readers who have seen the large *Luculia gratissima* growing in the cold conservatory at Thorpe Perrow, will be pleased to learn that it is now furnished with over 500 heads of bloom, in different stages of development—a grand object at this dull season of the year.

— DR. KING, superintendent of the Calcutta Botanic Gardens, states that the propagation of the *Ipecacuanha* plant by root and leaf cuttings has been so successful that there is at present in the Gardens a stock of 63,000 living plants; whereas four years ago there were but twelve cuttings, of which seven were afterwards accidentally destroyed.

— AT Nismes, in the South of France, the Japan Wax tree (*Rhus succedanea*) has lasted through six seasons, though it has been cut to the ground by frost more than once. The *Laurus camphora*, after giving hopes, has proved too tender. *Andropogon squarrosus*, an exceedingly fragrant Grass, has withstood the most severe seasons. All attempts to naturalise the *Eucalyptus globulus*, however, have, it is said, failed.

— THE annual festival of the Edinburgh Lodge of Free Gardeners took place the other evening in the Oddfellows' Hall. Mr. John Noble occupied the chair, after the reception of deputations from several sister lodges, addressed the meeting. It appeared from his remarks that the Edinburgh Lodge now possesses a capital of £3,000, and a membership of 300; and that its friendly society, which has been in existence for fifty years, is in a very prosperous state, having, during the period referred to, paid to its sick members £5,589 9s. 7d., and funeral money £2,195 10s.

— WE suspect there are so few who flower the beautiful *Orchis maculata* under cultivation, even in its ordinary season of blooming, that were we to ask "Have any of our readers tried to force it?" we should probably get ridiculed for our pains. Nevertheless, the *Farmer* says that the plant is amenable to such treatment, and that Messrs. James Cocker & Sons, of Aberdeen, force batches of it annually. This firm annually obtains fair sized samples of its tuberous roots from Holland, and pots them as soon as they arrive—generally about New Year's Day. When potted, they are put under the stage of a cool greenhouse, where they remain until growth commences—the subsequent treatment being in all respects the same as for *Hyacinths*—and they are said to grow and flower quite as freely.

— THE Shah of Persia appears to have been greatly struck with the beauty of European gardens. The entries in his diary, as he emerged from the vast and uninteresting plains of Russia to the more highly cultivated land of parts of Germany, are full of simply-expressed admiration for European horticulture. He says, enthusiastically, "Human improvements of charming aspect came into sight near and afar," remarking, with great admiration, the trees, flowers, and cultivated fields; and observing that the *Jasmine* of Sherwan, which Europeans call *Lilac*, was everywhere in luxuriant bloom. Over extensive districts, he exclaims, all was cultivation, avenues, forests, flowers, and meadows. The gardens at Potsdam appeared to him a world of delight. On reaching the Rhine he jots down still more vivid expressions of praise. The Rhine he declares to be a paradise, with its valleys and Vineyards. The extensive cultivation of the Vine and the Cherry tree appeared to him marvellous, especially the Cherry trees, which he found laden with fruit far more delicious than the Cherries of Persia. He thus describes the Vineyards of the Rhineland:—"Each Vine was bound to a strong stake; and the whole hill-sides and plain are one continuous Vineyard, from which the famous Rhein-wein is produced. The whole region is, indeed, a garden; mountains and plains are covered with

Vines, fruit trees, and flower gardens." But European horticulturists must not allow themselves to be too much elated by the praises of the Shah, as he appears to have been equally delighted and gratified with the astonishing beauties of the wax-works at Madame Tussaud's.

— IN China a liquor is distilled from the flowers of the *Chrysanthemum* which is regarded as an elixir vitae, and in the Chinese pharmacopœia a powder of the flowers is prescribed as a cure for drunkenness.

— A MR. RICKETTS, of Newburgh, New York, is stated to have raised a very remarkable set of seedling Grapes, of fine flavour and general qualities. They are the result of crossing the native American Grapes with some of the best European kinds.

— AT a late meeting of the scientific committee of the Royal Horticultural Society, Professor de Barry was disposed to believe that heterocism occurred in the case of the Potato parasite, that is to say, that part of its life was passed upon some other host besides the Potato. Mouillefert had recently suggested that this might be Clover, and Mr. Jenkins, secretary of the Royal Agricultural Society, supposed that both Clover and straw might harbour the unknown stage of *Peronospora infestans*, and that this "would justify the prevailing opinion that farm-yard manure encourages the ravages of the Potato disease, especially when applied in spring, because the spores of the fungus would be in the manure which had been used for litter."

— OF *Cymbidium giganteum*, a noble species well worth growing, we have just seen a fine specimen in flower in Messrs. Lucombe, Pince, & Co.'s nursery, Exeter, where it is bearing eleven fine flowers on a stout curved sub-erect or nodding spike. Its foliage is sheathed at the base around a short spindle-shaped pseudo-bulb. Each leaf is from 2 to 3 feet in length, and about an inch in breadth, of a deep green colour, and having about seven pale yellowish longitudinal veins. The individual flowers measure fully 3 inches across, the oblong sepals and petals being of a pale yellow colour, streaked or slightly tessellated with purplish-brown. The three-lobed lip is yellow, suffused with brown, and it has a two-lobed hairy crest running from the base to the apex. The column is vividly streaked with purple, and is terminated in front by a clear yellow anther case and appendages. When liberally treated, it is a beautiful species, which well deserves a place in collections.

— ALL who are interested in London gardens will learn with much pleasure that the Duke of Bedford has commissioned Mr. Meston to re-arrange and, in part, re-plant Bedford Square. The old specimen trees in our neglected London squares are by far the finest we have ever seen in any city, and the capabilities, so to speak, of these squares are, in other respects, so remarkable that a little good gardening and good taste are all that is required to make the old squares of London very beautiful. We trust that in the improvements of these squares, which this step of the Duke's may happily inaugurate, the designers will not spoil the quiet beauty of the shrubs and trees by the introduction of stonework, fountains, &c., by the display of which a garden is often greatly marred. There is, as yet, plenty of room for the display of the architect's skill on our houses, and public buildings, and, so far as squares are concerned, Nature and a good gardener are much to be preferred to cut stone and the architect, while the disadvantage, as regards economy, is all with the latter.

— THE Rev. George Henslow read a paper the other day on "Mechanical forces in plants" at a meeting of the West London scientific association. The paper was illustrated by diagrams and dried specimens. As regards rudimentary structure, he observed that although formerly the possession of the power of voluntary motion in plants was denied, it was so no longer. Animals and plants, he said, resembled one another in very many points, as, for instance, in the property of contracting on irritation. The contraction of the leaves of the sensitive plant, under an external stimulus, was almost identical with that of the tentacles of the Sea Anemone. The tendrils of the common Pea were observed to wave about almost as if by the power of volition, until they came in contact with a stick, when they clung to and wound round it. This power of contractibility evidently resided in the protoplasm, which had a common basis both in animals and plants. A plant it was said, sometimes exerted enormous force by the mere act of growth. With such force, indeed, did vegetable growth go on, that it was common to see stones and walls displaced by the process of root-growth. In the Rose of Jericho, and many other plants, including the delicate Mosses, they had also examples of hygrometric force. The paper concluded with notices of the employment of levers of three kinds in connection with the fertilisation of plants by the aid of insects, in the cases of the Garden Sage, the *Arbutus*, and *Sainfoin*, and of a modification of the screw or inclined plane in the Scarlet Runner.

MY GARDEN IN AUTUMN.

I HOPE you will allow me to make some remarks on the glory of autumnal tints—a somewhat hackneyed subject perhaps—but it is impossible to look without admiration on the scene that lies before me. Rocks and dells, woods and groves, sunshine and shade, the mossy rock surfaces half clothed with varied vegetation, and presenting the utmost richness of colour. The continuous heat of the late abnormal summer, succeeded by almost daily rains, have kept the foot-stalks of the leaves constantly growing, so that the leaves of nearly every tree and shrub were retained till almost the middle of November, and presented a scene of marvellous beauty. Besides the russet and golden hues of the Oak, Beech, Birch, Chesnut, Ash, and Larch &c., which contrast so finely with the dark sombre masses of Yew, Holly, Portugal Laurel, Bay, Pine, and Fir, there are a vast number of lesser shrubs and trees whose leaves “die so sweetly,” and seem to “snatch a grace beyond the reach of art,” that I feel it almost a duty to name and describe some of them, and perhaps the most beautiful is *Smilax rotundifolia*, that paragon of ramblers; although the berries are seldom matured in this country, as they are in Rome, its leaves in late autumn are transcendently lovely, varying from the most vivid green to citron, and from golden-yellow to russet and rich brown. It is invaluable to climb over rocks and stubbs. No less lovely is *Liquidambar styraciflua*, including all tones of warm hues, besides deep green and purple. Scarlet Oaks and crimson-leaved claret Vines should have the sun's rays transmitted through them, as also *Acer japonicum polymorphum*, one of the many valuable shrubs introduced from Japan by the late John Gould Veitch, and his *Ampelopsis tricuspidata*, both culminating in the richest crimson and purple foliage. Among the many plants which pass off into yellow—Tulip-tree, Dogwood, Euphorbia, Magnolia, *Ledum conspicuum*, and the large *Polygonum* (glorious as a background) are the most prominent. Next the golden amber tones of the Maples, *Rhus Cotinus*, *Aralia japonica*, Chestnut, Beech, Horse Chestnut, and Birch. These are followed by the fine crimson of the old Virginian Creeper, different kinds of *Rhus*, *Photinia*, and others; also by several of the Barberry tribe, Guelder Rose, Cornus, Azaleas, &c., then the constantly changing tones of Brake, Strawberry, and Bramble; and nothing can be more beautiful in general effect than the latter. Contrasting with the above are the glaucous grey and silver of Eucalyptus, of many of the Junipers, of the Lawson Cypress, Yuccas, Echeverias, and Aloes. Completing the picture, every nook and spare surface teems with Polypody, Bilberry, Cotoneaster, Hypericum, Heaths, Ivies, Ferns, Sedums, Saxifrages, rock and Alpine plants, while masses of Holly, Laurel, and Rhododendrons close the scene.

Glen Andred.

A POTATO CORRESPONDENCE.

THE following correspondence between Prof. Dyer, of the Royal Horticultural Society, and the Secretary of the Royal Agricultural Society, possesses some interest for horticultural readers:—The paragraph which appeared in last week's *Nature* is so far interesting that it amply confirms the expectations of those who have watched the well-meant efforts of the Royal Agricultural Society with respect to the Potato disease. I wish to advert to it for two reasons. In the first place, it is interesting to see the way in which a matter of this kind is regarded by so influential a body. Here is a disease annually effecting the destruction of a larger or smaller part of a chief item in the food of the community, which has already produced a famine in one of the three kingdoms, and any year may produce another, and which for the last thirty years has seriously occupied the attention of scientific men throughout Europe. It is not surprising that the Royal Agricultural Society should think the offer of a £100 prize for an essay in any way an adequate method of dealing with the subject? In the first instance, the time for sending in the essays was actually fixed, so as to prevent the competitors from even going over the life history of the Fungus during one season before competing. This was pointed out, and the time was prolonged. But though the competition was advertised abroad in the German papers, nothing of any importance was elicited beyond what was already well known. The society then determined to offer prizes for disease-proof Potatoes. The utter futility of this proceeding was clearly obvious to anyone in the least acquainted with the subject. But

it was done, and possibly if the “botanic referee” liked travelling about the three kingdoms, his time was not wasted. But the result is exactly what it was predicted it would be. Now, it seems to me that this spasmodic and ill-considered way of dealing with a serious subject contrasts, to an extent that it is impossible quite to regard with satisfaction, with the course that would be adopted in such a matter in other countries. It shows, at any rate, how little the methodical scientific method of investigation is understood by the majority of well-informed English people. And this brings me to my second point. The society, anxious not to be entirely foiled, offered a sum of money to a well-known investigator of the life history of Fungi, Prof. de Bary, of Strasburg, to induce him to study the Potato disease. Considering that De Bary had already written an admirable memoir on the Peronosporæ, there was a certain simplicity in supposing that the gift of a sum of money would elicit some additional information which his zeal as a scientific investigator had failed to do. If it does, however (and the history of the Peronospora infestans is not perfectly understood), it will be a clear gain; but when we are told that “Prof. de Bary has worked out the scientific questions that occur as to the origin of the disease,” and that “it is owing to a Fungus (*Peronospora infestans*) which attacks the leaves first, and after absorbing the nutriment of them, utilises the petiole, and thus reaches the tubes” (*sic*), it is necessary to point out that all this and a good deal more was ascertained by the Rev. M. J. Berkeley in this country, and by Montagne in France, and published by the former in a paper contributed to the first volume of the *Journal of the Horticultural Society* in 1846.

W. T. THISELTON DYER.

My attention has been drawn to a letter in *Nature*, vol. xi., p. 67, signed “W. T. Thiselton Dyer,” and headed “Royal Agricultural Society and the Potato Disease.” It appears that Prof. Dyer has founded the statements and criticisms in that letter upon a paragraph which appeared in the preceding number of *Nature*. Had he taken the trouble to read the official reports that have been published by the Society in the agricultural newspapers, the criticisms he might then have made would probably have had some value; and I must express my surprise that a man of scientific pursuits should have omitted to take that most necessary and most elementary course which I may term the verification of fundamental facts. This is the more remarkable as he criticises the Society's want of “methodical scientific method of investigation.” Prof. Dyer asks, “Is it not surprising that the Royal Agricultural Society should think the offer of a £100 prize for an essay in any way an adequate method of dealing with the subject?” Now, what does Prof. Dyer mean by this question? He seems to imply that the Royal Agricultural Society offered such a prize, and that therefore they thought it an adequate method of dealing with the subject. But the society did not offer such a prize, and have not considered whether such a method would or would not be adequate to deal with the subject. The truth is, that Lord Cathcart offered such a prize two years ago, and asked the Council of the Society to nominate the judges and otherwise to take charge of the competition. This they did, and for this alone are they responsible. Prof. Dyer proceeds: “The society then determined to offer prizes for the disease-proof Potatoes.” To this I must beg leave to reply that the society did not offer prizes for “disease-proof Potatoes,” but for Potatoes which should resist disease for three years in succession in twenty different districts of the United Kingdom. If the somewhat lengthy statement of the terms on which the prize was offered has been colloquially abbreviated into “disease-proof Potatoes,” that does not justify a scientific man in basing an argument upon it, especially in the columns of a scientific journal. Professor Dyer continues: “The utter futility of this proceeding was clearly obvious to anyone in the least acquainted with the subject.” Here again I must join issue with the Professor. This prize was offered because certain essayists asserted, and seedsmen advertised, that they possessed varieties of Potatoes which would resist disease. To put these statements to the test was in conformity with the society's ordinary practice, which is to endeavour to make its members acquainted with the actual agricultural value of various articles, whether they be seed-Potatoes, manures, implements, or other commodities. As the result has been to show that none of the Potatoes experimented upon can resist disease for even one year in our twenty stations, the members of the society now know what value to attach to the assertions of their proprietors, and the result is, therefore, not utterly futile. These experiments have also been utilised to ascertain the influence of soil, climate, and modes of management on the crop itself, and on the Potato disease; and the results of this inquiry are now being worked out. Professor Dyer goes on to say—“Now, it seems to me that this spasmodic and ill-considered way of dealing with a serious subject

contrasts, to an extent that it is impossible quite to regard with satisfaction, with the course that would be adopted in such a matter in other countries. It shows, at any rate, how little the methodical scientific method of investigation is understood by the majority of well-informed English people." I am content to ask Prof. Dyer to point out what is "spasmodic" and what is "ill-considered" in the action of the society, and how does he justify his assertion about "the methodical scientific method of investigation?" It must be remembered that the Royal Agricultural Society was not established for the advancement of science, and certainly not for the advancement of botany; but it was established for the promotion of agriculture, especially by the encouragement of the application of the discovered truths of science to the practice of agriculture, as is shown by its motto, "Practice with Science." The Royal Agricultural Society does, however, enlist the services of scientific men upon its regular staff, and in this and other ways seeks to direct their attention to agricultural problems upon which the light of science is still wanting. As Prof. Dyer has contrasted the society's "spasmodic and ill-considered way" with "the course that would be adopted in such a matter in other countries," I hope that he will inform me of the course that agricultural societies in other countries have adopted in reference to the Potato disease and other such matters, without receiving assistance from the government of the country. I now come to what Prof. Dyer calls his "second point." He states that the society, "anxious not to be entirely foiled, offered a sum of money to a well-known investigator of the life-history of Fungi, Professor de Bary, of Strasburg, to induce him to study the Potato disease. Considering that De Bary had already written an admirable memoir on the Peronospora, there was a certain simplicity in supposing that the gift of a sum of money would elicit some additional information, which his zeal as a scientific investigator had failed to do." So far as I understand the meaning of the phrase "anxious not to be entirely foiled," it implies some previous disappointment. Now, so far as this from having been the fact, that the first step taken by the council of the society was to direct me to write to Prof. de Bary and urge him to continue his researches into the life-history of *Peronospora infestans*, in view of the vast importance of the subject in its agricultural bearings. Therefore I cannot see how the term "anxious not to be entirely foiled" can be made applicable to it. The society at the same time volunteered to place a sum of money at his disposal towards defraying the expenses which he might find it necessary to incur, but I hope that my communication to Prof. de Bary was not conceived in the offensive spirit which Prof. Dyer seems to suggest. The principle involved has been adopted by the British Association as one of the best means of advancing science, and I consider it a very different matter from that "certain simplicity" which Prof. Dyer derides. This was not only the first, but it was the only step then taken by the society in reference to the scientific questions bearing upon the Potato disease; and its results up to this time are in no respect indicated by the grotesque statements which Prof. Dyer quotes.

H. M. JENKINS.

HORTICULTURE AT THE INTERNATIONAL EXHIBITION OF 1876.

THE Horticultural Hall is one of the five principal buildings which the United States Centennial Commission will erect for the accommodation of the International Exhibition of 1876, at Philadelphia. These structures—the industrial hall, or main exhibition building, the machinery hall, the horticultural hall, the agricultural hall, and the art gallery—will have an aggregate flooring of about 40 acres; but the industrial and machinery halls have been so designed that they can be enlarged to almost double the capacity originally allowed, should the demands for space require it. The horticultural hall has been designed by Mr. H. J. Schwarzmann, under the supervision of the National Horticultural Society. Its materials are glass and iron, its length 310 feet by 160 in width, giving an area of 14 acres. The greater portion of this space is devoted to the grand conservatory, which is 227 feet by 77, and occupies the central portion of the building, there being between it and the outer walls on either side the warm and the cold houses, and at the ends, on the right and left of the entrances the dining-halls, offices, retiring-rooms, &c. In close proximity to the horticultural hall will be a number of subsidiary structures—a *Victoria Regia* house, domestic and tropical orchard houses, a Grapery, and other horticultural structures. The surrounding grounds, including a large tract, may be extended almost *ad libitum*, and will be arranged for out-door planting, which will constitute the larger portion of the horticultural display. It is proposed to plant, at least a year before the opening of the exhibition, the representative trees of all parts of this Continent. The visitor, it is intended, shall see side by side the full variety of the forest

products and fruits of the country, from the Firs of the extreme north to the Oranges and Bananas of Florida, and Grapes and other fruits of California. An impression will thus be produced of the fertility of the land, and of the vast range and diversity of its products, of which few persons have any conception; and the exhibition, according to the *American Agriculturist*, will be without a parallel for extent and completeness. In addition to the strict horticultural display, careful provision will be made in advance for trials of agricultural machinery. At the disposal of the Centennial Commission are 450 acres of land, within the limits of Fairmount Park; and a considerable portion of this, divided into lots of suitable size, will be put into crops, for the purpose of testing the mowers and reapers and other agricultural implements offered for competition. About a year ago a National Horticultural Society was organised for the express purpose of co-operating with the Centennial Commission, and its various committees are composed of some of our most active amateur and professional horticulturists. The matter is in good hands, and we may hope to see a fine exhibition in 1876.

FERN CASES.

FERNS are plants which give little trouble, yet they are seldom to be found in sitting-rooms. For those who do not possess a large Fernery there can be no more interesting or pleasing occupation than attending to and watching the growth of these plants in their miniature house. Wardian cases may be purchased at a small or large outlay, according to size or ornamentation, but plain cases are quite as suitable as those that are ornamental. Where there is room, I like to see rather a large-sized case, in which large Ferns can be accommodated, and also a few small suspended baskets. As regards cultivation, the first thing that demands attention is the drainage of the case, for, if that is defective, neither Ferns nor other plants can be cultivated successfully. In order to secure good drainage the case should be fitted with a false bottom, into which the water may drain through perforated zinc or iron, on which the rock-work and little banks for the Ferns should be placed. The false bottom being a kind of little tank or drawer, if I may so term it, should be perfectly water-tight, so as to protect the carpet, and should have a little tap fixed in one corner of it, by means of which the surplus water, drained from the Ferns, may be drawn off. To be able to give free ventilation to the plants every morning is another essential point, as a stagnant atmosphere is almost as injurious as stagnant water. Over the perforated tray of the case a good layer of broken crocks should be laid, and these should be covered with Cocoanut fibre, on which the rock-work should be set. The space in which it is intended to grow the Ferns should then be filled in, and I may say nothing is better for this purpose than peat, rotten turf, and sharp grit sand. In the parts of the case intended for the planting of rather strong-growing Ferns, a larger proportion of rotten turf should be mixed with the peat than in those intended for less robust varieties. The next thing to be considered is, what kind of Ferns to plant in the case. I should recommend some of the following:—*Acrophorus chærophyllus*, *A. hispidus*, *Adiantum cuneatum*, *Anemia adiantifolia*, *Asplenium striatum*, *bulbiferum*, *Pteris serrulata*, and all kinds of *Trichomanes* and *Selaginellas*. If the Fern case be large it might be advisable to have an arch reaching from end to end, over which could be trained two plants of creeping Fern (*Lygodium scandens*), one planted at each end. From the centre of the arch a tiny basket filled with *Selaginella Martensii variegata* might be suspended. In planting Ferns care should be taken to place the dark green varieties next the light; in fact, to produce light and shade, and not to plant them just as they come to hand.

Stands of Plants.

Another favourite style of indoor decoration is wire stands filled with pot plants; some have them so that the plants can be arranged in tiers one above the other; but I prefer a flat stand like a table, on which the plants can have plenty of Wood Moss packed round the pots. It is a good plan during summer to wash the Moss well with water, before placing it between the pots; but care must be taken to squeeze all the water which it contains out of it, otherwise it would be liable to drip; damping the Moss, however, tends greatly to keep the plants fresh during the hot summer months. *Dracænas*, and hardy Palms are well suited for this style of decoration, but they require to have their leaves spooed now and then. Once a week will be often enough to water plants set in Moss; the plants should be lifted out of the stand, well watered, and, as soon as drained, returned to their respective positions; flowering plants, when they can be obtained, may be intermixed with the Palms and other foliage plants with good effect. Stands such as these are well suited for the decoration of a vestibule.

A. HASSARD.

THE INDOOR GARDEN.

FORCING GLADIOLI.

Few plants are more beautiful than Gladioli forced into bloom early in spring, either as cut spikes for the drawing-room, or in pots for the conservatory. For such purposes it is, however, essential that the bulbs should have been thoroughly well grown and well ripened; as it is a waste of time to pot weakly ill-developed bulbs, and the forcing should be carried on gently, in order to secure strong spikes. The hybrids of *Ramosus* and *Cardinalis*, are the best for early forcing, inasmuch as they bloom naturally earlier than the *Gandavensis* section; but some of the latter may be potted for late successions. They may be potted anytime from October onwards, according as they are required to be in bloom, early or late, and may be covered with old tan or sawdust, in a cool place, and introduced into heat as required in succession. About three bulbs in a 32-sized pot, will make a nice potful, or very strong bulbs may be potted singly in 48-sized pots. The soil should be turfy loam, well broken up, with about a third of well-decayed leaf-mould, or old hot-bed manure, and a good sprinkling of charcoal dust or sand should be added; bury the bulbs about an inch deep, and give them a good watering to settle the soil. The best place in which to start them is a low pit filled full of leaves, such a pit as is commonly used at this season and onwards for starting early Strawberries. The pots should be plunged in the bed, and a few leaves should be scattered over their tops to keep the soil in an even state of moisture without having recourse to the watering-pot before active growth begins. As soon as the spikes appear, the pots should be removed to the forcing-house and placed near the glass to be afterwards hardened off for the conservatory or drawing-room. When the plants have done blooming they should be removed to a deep cool pit to finish their growth; and, after undergoing the usual ripening process, they should be planted out the following year and fresh bulbs selected for potting.

E. HODDAY.

EPIGYNUM LEUCOBOTRYS.

SEVERAL species belong to this genus all of which are well worth cultivating as ornamental greenhouse shrubs; but *E. leucobotrys* is undoubtedly the best at present in cultivation. It was brought into notice by Messrs. E. G. Henderson many years ago; but never seems to have become very popular—a singular fact when the beauty of its waxy black-

spotted opal berries, and the freedom with which they are produced, are taken into consideration. This plant is well figured in the *Botanical Magazine*, and also in Messrs. E. G. Henderson's "Illustrated Bouquet," from a specimen grown in the Wellington Road Nursery. Our attention has been recently directed to this pretty berry-bearing shrub, through a plant of it in fruit having been lately exhibited to the Floral Committee of the Royal Horticultural Society, by Mr. Parker, of Tooting. The root of this shrub is somewhat singular; it is thick and swollen like that of a Chinese Potato or Yam. Its stems and branches are terminated by tufts of bright glossy green leaves, and, from among these, drooping racemes of white, black-dotted, berries are produced as shown in our engraving.

Epigynum leucobotrys.

Mr. Gumbleton informs us that it has proved quite hardy with him at Belgrove, in the south of Ireland, where it has withstood the last two winters unhurt. The blossoms, which are, individually, small, pale, and insignificant, resembling those of an *Arbutus* or *Andromeda*, are produced in abundance, usually from the centres of the whorls of leaves which terminate the young growths of the year, the intervening stems being invariably quite bare and leafless, which give the plant a somewhat peculiar aspect. A raceme of bloom, however, occasionally pushes out of the hard bare stem between the whorls of leaves, a circumstance which somewhat relieves the plant of its monotonous appearance. The blossoms are short lived, and set their fruit almost immediately, and in great abundance. The berries, however, take a considerable time to swell to their full size and attain the pure ivory whiteness which makes them resemble, when at maturity, a round bone or ivory stud, relieved and ornamented by a clearly-marked jet black central dot, surrounded, as shown in the engraving, by a ring and five smaller dots of the same contrasting colour, giving the fruit a most unique and ornamental appearance. The berries reach their full development about the commencement of the month of September, and remain on the shrub nearly the whole of that month. This interesting plant has, as we have stated, been long ago distributed by Messrs. E. G. Henderson, but those to whom they supplied it do not seem to have succeeded with it; probably, from taking too much care of it. The plant is evidently as uncommon as it is beautiful, but we hope, now that it has again been brought into notice, to see it more generally grown than it hitherto has been. The different species of *Epigynum* are East Indian shrubs, thus named in consequence of the disc which surmounts the ovary. They constitute a genus of *Vacciniaceae*, known by their five-parted flowers, and bell-shaped or cup-shaped corolla.

B.

CULTURE OF THE CHRYSANTHEMUM.

It is now over a hundred years since the Chrysanthemum was first introduced to the gardens of this country, and but little progress appears to have been made in its improvement until within the last thirty years, when the late Mr. Salter took it in hand, and year after year produced varieties—improvements both in form and colour. Others have contributed both seedlings and sports—that is, a flower identical as to form and general habit with the plant from which it springs, but differing in colour, such as we see in many of the most popular sorts; as, for instance, the unapproachable variety for general purposes, Mrs. Rundle, a moderate-sized incurved white, from which was produced as a sport the equally fine yellow, George Glenny. Many other established favourites have similarly sported, such as the fine *Bronze Jardin des Plantes*, from the bright yellow kind of that name. Golden Beverley sported from Blush Beverley, and numbers of others owe their origin to the disposition in the Chrysanthemum to diverge more frequently than most plants, from the colour of flower which, as a seedling, it possessed. Although much improvement has been effected in the Chrysanthemum, still its cultivation has not extended nearly so far as might have been expected from the numbers of ways in which it can be used in decoration, its unlimited and easy propagation, freedom of growth, adaptability to any soil if sufficiently enriched, and an ability to grow and flourish where few other plants can be made to exist. It must not, however, be inferred from this, that the Chrysanthemum is indifferent to good treatment; on the contrary, that it likes it, is evident from the results that are seen when it meets with liberal culture, based upon attentive observations as to its natural habits and requirements. It is to the character which the plant has for being able to exist under neglect and bad usage that is to be attributed the indifferent condition in which it is so often seen, even where better things might be expected.

Propagation and after Treatment of Cuttings.

The propagation of the Chrysanthemum may be effected in various ways, but for general purposes cuttings are the most satisfactory, especially for pot culture. The time at which they should be struck should be determined by the time and purpose for which they are required. If for exhibition, or even home decoration, I prefer taking the cuttings off as soon as they can be obtained in December or January; they should, as far as possible, be taken from plants that have not been too much weakened by over-crowding. Get them about 3 or 4 inches in length, remembering that with these, as with most other plants, a good cutting will generally keep ahead of a weak one through the first stages of the plant's existence, and, in the case of things annually propagated in this way, the weakly ones rarely overtake the stronger. Insert them, two or three together, round the edge of 60-sized pots (first removing with a keen-edged knife about one-half the bottom leaves), in equal parts of sand and good loam; give them a liberal watering, and remember, from the day the cuttings are inserted until the plants have flowered and are done with, never to let them get dry. This is of the greatest importance in the cultivation of this flower, either in pots or the open ground. The cuttings should be placed under a bell-glass in a cool greenhouse or garden frame, where frost can be excluded. They will require the soil to be kept moist, and any leaves that decay must be removed. As soon as they have made roots they will commence growing, when the glass must be removed to give them full air. They should then be moved, singly or in pairs, into 3 or 4-inch pots, in good soil, well enriched with rotten dung and leaf mould, if such is at hand. Always use enough sand to keep the soil porous, as the quantity of water the plants in their after stages require necessitates plenty of drainage. Keep them near the light, and when they have grown a couple of inches pinch out the points, to induce them to break. As soon as they have filled their pots with roots, move them into others 2 or 3 inches larger, using as before good rich soil. If kept in a greenhouse or pit through the winter, by the beginning of April they should be removed to a cold frame, off which the lights can be taken on mild days. As their pots become filled with roots, attend well to them with water, and by the end of May remove them into their flowering pots, which may measure from 8 to 12 inches in diameter, using soil composed of three parts loam, one part rotten dung, and one part well-decomposed leaf mould, with enough sand to ensure the water passing freely through it; pot moderately firm. By this time they will again require stopping; plunge them at once in coal ashes. Many defer this plunging of the pots until the plants become larger; but the soil in a pot fully exposed to the open air, if not plunged, fluctuates in temperature day and night with that of the air, in a way not conducive to free growth. When they have broken after this second stopping they will consist of from six to eight shoots, which, as soon as long enough, should be tied out to neat

sticks placed just inside the pots, sloping considerably outwards so as to keep the plants open. See that they stand in a good light situation, so as not to become drawn up, as they inevitably will if too near trees or high walls; yet they must not be too much exposed, or strong winds will be liable to break them. To afford a succession, a portion, especially the latest flowering sorts, should be again stopped at the end of June; after this time they should be syringed every evening. This not only assists the growth of the plants, but is the best remedy against green fly. As the roots now begin to take full hold of the soil, commence to give them manure-water every other time they are watered. Some growers do not recommend this being given until the plants have shown bloom; but, by so deferring its use, neither so many nor such fine flowers or foliage will ever be secured. It is somewhat difficult to convey an idea of the strength they will bear. The finest I ever had were fed from a tank in which the drainings from the cowsheds were caught, unmixed with rain or any other water. This was given them diluted in the proportion of one gallon to two of water every other day for a time, and after they had set their flowers they received very little pure water, except the syringings overhead. It is the want of sufficient sustenance in the shape of this liquid feeding, and negligence in allowing them to get dry, that causes them to become naked at the bottom, a circumstance which destroys half their beauty. Keep them well tied out to the sticks, so that they may not get broken with the wind. As soon as the flowers are formed and large enough to handle, they should be thinned.

Thinning the Flowers and Subsequent Management.

We have so far been treating of plants for general use, such as home decoration, not for purposes of exhibition, and more particularly in respect to the cultivation of such varieties as are best adapted to the purpose, by their ability to perfect a large number of flowers without regard to extraordinary size; but, even if there is no intention of growing them for exhibition, all except the Daisy-like *Pompons* should have their flowers thinned. By this means they will not only become much larger individually, but will last on the plants much longer than they otherwise would. This I have proved often by observing the difference between such as were thinned and such as were left untouched. In addition to the shoots that are induced to break by the stopping already recommended, the plants will, just previous to setting their flowers, branch out considerably, forming three or four shoots on each that already exists, the flowers on all of these, in the case of the medium-sized varieties, should be reduced to two or three, and the great quantities of small side shoots that are formed (more or less according to the character of the particular variety), all the way up, with their small flowers, should be removed as they make their appearance, as well as all suckers from the collar of the plants. Now, whilst the flowers are swelling, and consequently taxing the energies of the plant to the utmost, is the time when they should be carefully supplied with water; in hot weather they will require it twice a day. Every fortnight, from the time when the pots have got full of roots, turn them round in the hole they occupy in their bed of ashes, so as to prevent the roots that come through the bottom laying hold outside. To still further prevent this, a good large hole may be made in the soil with a crowbar, considerably deeper than the bottom of the pot will reach. Do not leave the plants out so as to endanger their injury by frost; the end of September is as late as it is safe to trust them, even in the south. Where a slight framework exists, that will carry a canvas covering that can be thrown over them at night, they will be safe; but, although a hardy plant, their time of blooming is so late in the season that their flowers are endangered if subjected to too much frost. An early Vinery, where the leaves are nearly all off, and where they can have air on at all times, with a very small amount of heat in the pipes during wet damp weather, answers well for them; some may be placed on the south side of a wall, and if there is a north or retarding house, late varieties, such as were the last stopped, should be placed here for succession. Should mildew make its appearance upon the leaves after the plants are placed in the houses where they are to bloom, flowers of sulphur should be at once dusted upon the affected parts; but, to prevent this, it is better to use a little warmth occasionally, with top air on, so as to cause a little motion in the atmosphere. Whilst here, they must not be allowed to suffer want of water; but, as the flowers get nearly expanded they will not require manure-water, which would be objectionable in several ways.

Planting-out System and Layering.

Chrysanthemums can also be grown well by training them out into a good bed of prepared soil at the end of April, instead of potting on in the spring, and then planting them sufficiently far asunder, in an open situation, so as to induce sturdy growth. Here they require stopping,

staking, and tying, just as if they were in pots. They must also equally have their wants supplied with water, both pure and manurial, as also their syringing overhead, which, if persisted in, is an almost certain preventive of aphides. Immediately after the blooms are fully set they should be taken up and potted, giving them a good soaking with water as soon as they are placed in the pots. They should then, if possible, be put for a few days in a north house, and kept close, with little air admitted, until they have begun to root, which will be in a week, during which time give them pure water enough to prevent the least flagging, or the leaves will suffer, after which gradually give them air, and in a fortnight they will bear full exposure, when the flowers must be thinned, and plenty of manure-water given. But this planting-out system of culture is best adapted for producing large flowers for cutting, where the plants, instead of being stopped to produce a bushy head, have been confined to two or three shoots, and where there exists a house in which they can be transplanted from the open air into a bed of rich soil prepared for the purpose, where they can be moved with their roots little mutilated, a circumstance that must take place when they have to be placed in a limited-sized pot; here they just require as many stakes and ties as will support them, and for this purpose they need thinning (especially if the object be to exhibit cut flowers), so as to concentrate all the powers of the plant in a few blooms—from two or three to a plant up to half-a-dozen, according to the natural capabilities of the variety to perfect a greater or less number. The larger the flowers produced by any sort, the fewer, as a rule, it is able to carry. Where the planting-out system is followed for pot culture, there is another and a better method of managing them in their later stages of growth. Instead of stopping the last time they should be encouraged to make as many shoots as possible on the top of the main stems; and, as soon as the flowers are formed, the principal stems should be bent down to the ground and layered just under the head of small flowering shoots; this should be done by pegging the shoots down with some sufficiently strong hooked sticks in little hills of sifted soil, made rich with rotten manure and leaf mould, with enough sand added, so that the roots, when formed, can be transferred to the pots without being much injured; these shoots must have the soil in which they are layered kept regularly watered. They will quickly root, during which time the flowers must be thinned, and, as soon as they have formed as many roots as will nearly fill the pots in which they are to be placed, the main shoot should be two-thirds severed and allowed to remain so for three or four days, then cut away from the stool and at once potted in rich soil, well watered, and placed in a house where they can be shaded and kept close for a few days; or they may be put near a wall and covered with canvas, supported on a temporary framework, for a week or ten days, until they have commenced to root freely, when they may be gradually exposed to the full air, but on no account must they be allowed to flag in the least or the leaves are certain to suffer. Feed them well with liquid manure until they have nearly opened their flowers. I have seen them transferred from where they were layered into the pots when the flowers showed considerable colour, and yet, with careful management, every bloom would open as fully as if they had never been moved. Where Chrysanthemums are grown up to a wall, as on the side of a cottage, and trained thereto, their treatment, so far as propagation goes, may be the same, or division of the roots may be resorted to, not using too large pieces. The principal thing to observe is to take them up every spring and remove the soil so far as their roots have extended, as they are such gross feeders that they completely exhaust everything within their reach; this must be replaced with good rich new soil, and instead of being, as is often the case, made higher than the surrounding ground, it should be an inch lower, so as to hold the large quantity of water they require, the regular supply of which must never be omitted if slightly plants and fine flowers are expected. Syringe them and train the shoots; and here some may be stopped a little later, for the protection afforded by the wall, and the opportunity it gives of a little covering on doubtful frosty nights, will enable the grower to cut many a fine bunch after they are destroyed in the open ground, in which case all the difference that there may be as to treatment is that they should not be so often stopped, in order that their blooming may be somewhat earlier, before there is much danger of frost, to still further ensure which the earliest flowering sorts should be grown.

Varieties for different purposes.

As decorative subjects for pot culture and furnishing cut flowers are the most general purposes for which Chrysanthemums are used, I propose, first, to notice such sorts as I have found best adapted for cultivating in that way. Amongst what are known as the large-flowered varieties those that produce blooms of medium size are by far the best suited to the requirements of ordinary growers, on account of their ability to perfect so many more flowers than such as produce the largest blooms, which are more fitting for the exhibition

stage, and which, if not thinned to a comparatively small number, have a loose ragged appearance, not filling up properly the centre of the flower.

Large Flowered Varieties.—*White*: Mrs. George Rundle, White Eve, White Venus, Mrs. Halliburton, Beverley, and White Christine.—*Blush*: Hermione, Isabella Bott, Her Majesty, Cassandra, Mrs. Hurlington, and Aimée Ferrière.—*Yellow*: George Glenney, Guernsey Nugget, Annie Salter, Aureum multiflorum, Jardin des Plantes, and Cherub.—*Bronze*: Robert James, Cardinal Antonelli, Mr. Gladstone, Bronze Jardin des Plantes, Bronze Annie Salter, and Mr. Evans.—*Rose, Lilac, and Pink*: Lady Talfourd, Princess Louise of Hesse, Purpureum elegans, Pink Perfection, Jane Salter, and Countess of Dudley.—*Purple and Crimson*: Julie Lagravere, Lord Derby, Progne, Fingal, and Josiah Wedgewood.

Large Anemone-flowered Varieties.—Fleur de Marie, Lady Margaret, Prince of Anemones, Bijon, Princess Charlotte, Margaret of Norway, and Louis Bonamy.

Pompons.—Mademoiselle Marthe, Madame Montels, Brilliant, White Travenna, Hendersonii, Andromeda, Hélène, President Decaisne, Saint Michael, Rose Travenna, Mrs. Dix, Miranda, Calliope, Grace Darling, La Foudre, Salomon, Andromeda rosen, Saint Thais, and Astrea.—*Japanese*: Grandiflora, Erecta superba, Fair Maid of Guernsey, Cry Kang, Red Dragon, Brown Dragon, Aurantium, and The Daimio.

The above kinds are such as are most suitable for the general grower for ordinary purposes, yet amongst them are also many of the best varieties for exhibition specimens in pots, being distinct and varied in colour, and possessing the natural capability to carry and perfect a large number of flowers—the first essential in a Chrysanthemum for either home decoration or the exhibition stages, and a property which the varieties that produce the best show-cut flowers, with few exceptions, do not possess. Yet, to produce the best effect with these most useful of all autumn plants, even for home adornment, a few of the varieties that make the largest and most perfect individual blooms should be grown. For this purpose the plants should be only once stopped and not allowed to carry more than from four to six flowers each. So treated, when placed in a group for conservatory decoration, they will stand up considerably higher than the rest of the plants they are associated with, and the size and quality of the blooms will form a pleasing contrast to the smaller samples that surround them. The most beautiful variety in existence, alike for its noble size, perfect form, and pure white colour, is Empress of India. This sort, well grown in a 12-inch pot, and allowed to carry about three flowers, will surprise any one who has not seen Chrysanthemums similarly treated. The following are a few that may with advantage be used in this way:—Prince of Wales, dark purple; Mr. Brunlees, Indian red; Lady Slade, distinct pink; Princess Beatrice, rosy-pink; Hero of Stoke Newington, rosy-blush; Plenipo, silvery shaded purple, large and fine; Mr. Stowe, orange-amber, very fine; Queen of England, very large white; Baron Best, reddish-chestnut; Venus, large pale lilac; John Salter, red, orange centre; Miss Maréchaux, white, with good substance of flower; Jardin des Plantes and Cherub, both yellow. Anyone commencing to grow Chrysanthemums for exhibition as cut flowers will not be far wrong with the following selection:—Countess of Derby, Empress of India, John Salter, Golden John Salter, Princess of Wales, Princess Beatrice, Jardin des Plantes, Isabella Bott, Mr. Gladstone, Lady Slade, Alfred Salter, Mrs. Heale, Mr. Brunlees, White Venus, Venus, Lady Talfourd, Mrs. Halliburton, Princess of Teck, Empress Eugénie, Rev. J. Dix, Mrs. Sharpe, Nonpareil, Antonelli, Thais, Golden Eagle, Gloria Mundi, Bronze Jardin des Plantes, Queen of Lilacs, Her Majesty, and Golden Nugget.

T. BAINES.

Araucaria excelsa speciosissima.—This is probably one of the prettiest kinds of the Norfolk Island Pine produced, and is a variety which is, above all, remarkable for its hardiness as well as for its appearance, which reminds one a little of the *Araucaria Cunninghamii*; but it is of larger size. We have admired it many times at the establishment of M. Rougier-Chanvière, who, with considerable trouble, has collected a large number of the varieties of *Araucaria excelsa*, such as we have never before seen. The distinguishing characteristic of the variety of which we are now speaking is, independently of its appearance and hardiness, the length of its leaves, which are very large and curved—in fact, curled up—and which reach a length of 4 centimètres, and then terminate in a sharp point. This curling up of the leaves gives to the boughs exactly the appearance of the *Araucaria Cunninghamii*, and appears to be an intermediate link between the two kinds. From whence comes this variety? We are unable to tell. All we can say is, that it is one of the most beautiful and ornamental of *Araucarias*, and that we have only seen it at M. Rougier-Chanvière's, where it may be obtained.—*Revue Horticole*.

PELARGONIUMS AT CHILWELL.

THE most interesting feature in connection with Mr. Pearson's nurseries at Chilwell, at present, is a long span-roofed house filled with fancy flowering Pelargoniums, which, as regards profusion and high colour of flowers, surpass anything of the kind I have ever seen, even at midsummer. They consist of what is known as the Chilwell "strain," having all been raised there. The trusses of many of them are nearly as large as the crown of a man's hat, and many of the individual blooms showed a considerable margin when placed under a half-crown piece. The plants, though not set very closely together, were wholly concealed beneath their load of bloom, and, when looked at from one end of the house to the other, although no green foliage stood out in bold relief, there was nothing approaching sameness. The colours were so artistically blended and brought out that I am sure the most capricious, as regards such matters, would have pronounced the display faultless. No such variety of colours could be found in any other class of plants, either in or out of doors, at this season of the year. White, pink, lilac, rose, rose-red, scarlet, light and dark crimson, salmon-red, rosy and purple-crimson, and magenta are only a few of the shades which might be enumerated. I am not very partial to the extensive use of Geraniums in the flower garden, as, in many places, they are too short lived to repay the trouble entailed in their culture; but such a display indoors as that at Chilwell would quite compensate anyone for any amount of trouble bestowed to produce it. Many of the new varieties, to be sent out next year, are superior to any previously distributed; but prominent among the whole was *Amaranth*, a kind which cannot fail to be a favourite. As a pink, I have seen nothing yet to equal it. In one group were ninety-nine varieties, all of Mr. Pearson's raising. I saw other things at Chilwell which greatly pleased me; but this Pelargonium show in the beginning of December I shall not soon forget. J. MURK.

Plant Growing in Glazed Pots.—It is generally believed that plants succeed best in pots which are most porous. Mr. Thomson, of Drumlanrig, entertains, however, a different opinion. More than half the Orchids, stove plants, Ferns, and even hard-wooded plants grown there are in pots which are thickly glazed from top to bottom, and the growth of one and all is wonderfully fine. The fine foliage plants are, indeed, marvels of health and bright colour, and many of the Orchids are unequalled in the country. Mr. Thomson informed me that, as the other plants, which are in common clay pots, require shifting, he intends substituting glazed ones, so that very shortly there will be no other kind of pot in use about Drumlanrig but glazed ones. The latter never become green or dirty looking, and all they require in order to renew their original gloss, when soiled in any way, is a rub with a rough cloth.—J. M.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

New Dark Neapolitan Violet.—This variety has much larger flowers than the common Neapolitan Violet, and, as a bouquet Violet, it is greatly superior to it; it also grows and flowers more freely, and it possesses, moreover, a lovely rich dark violet colour, very different from that of the ordinary kind. It is, in short, a distinct and valuable Violet, which, when better known, cannot fail to be appreciated.—G. BRUCE, *The Gardens, High Grove, Pinner.*

Should unhealthy Camellias be planted out or re-potted?—I have just had put under my charge thirty Camellias, ranging from 4 to 6 feet in height and very unhealthy. I am thinking of planting them out at the back of a Peach-house, but, before doing so, I should like the opinion of some experienced Camellia grower on the matter. Firstly, should they be shaken out or planted with their bulbs entire? Secondly, what is the best season for planting them? Thirdly, what kind of soil should I use? Fourthly, would they be better re-potted than planted out?—ENQUIRER.

How to Propagate Ipomœa Horsfalliæ.—Let those who have an old plant of this either in a pot or planted out, take as many of the tubers as can be spared from it, and cut them into 2 or 3 inch lengths; then cut from the plant some of the last year's growth for scions, each containing two eyes; now cut a piece out of the tuber and cut the scion so that it will exactly fit the incision; tie a piece of lint round it, put it in suitable pots, and place it anywhere in a stove or warm pit, and thus treated not one out of fifty will fail. Years ago I struck hundreds in this way; one named, I think, *mexicana*, I used principally for stocks; its tubers are more numerous, and not so large as those of *Horsfalliæ*.—W. DODDS, *Gladstone Villa, Bishopston, Bristol.*

Roman Hyacinths at the Manchester Show.—Beautiful pans of these Lily of the Valley-like flowers were shown at Manchester the other day by Messrs. Dickson and Robinson, and by Messrs. Dickson, Brown, and Tait. The fifteen pans shown by the first-named exhibitors, were in every way excellent, and the first prize was justly awarded to them; seldom, indeed, have such masses of pure white flowers been seen in December. The pans were done round with imitation green Moss, which had a pleasing effect. I have had pans ornamented in the same way for the decoration of a front hall, but instead of using green Moss, I employed sprigs of green Holly, well covered with berries, which answered admirably. I have also used berry-bearing Aucubas, round Snowdrops, in the same way and with excellent effect.—W. HINDS, *Otterspool Gardens, Liverpool.*

THE KITCHEN GARDEN.

FORCING VEGETABLE MARROWS AND OTHER EARLY PRODUCE.

WITH reference to the question asked by your correspondent, "T. S.," Limerick (see p. 529), permit me to say that Vegetable Marrows may be forced in the way he mentions. The seeds may be sown early next month, as the days will then be rapidly lengthening. Soak them previously to sowing in warm water, about 85° or 90°, till they show signs of bursting, then plant three seeds in a 48-sized pot, filling as many pots as will be required with soil that has been standing some hours in a warm place, and watering when necessary with warm water. Have the pit in a condition to receive the plants when strong enough to put out; good hills of rather strong loam should be placed in the centre of each light, packed firmly together and made high enough to raise the plants near the glass; as the material in the pit will be sure to settle as the season advances. If light rich soil is used, too much growth will be the result, and very little fruit. The plants may be earthed up when necessary, and as much firmness should be given to the soil as possible, in order to ensure strong short-jointed growth and a fruitful habit. After May, when the nights are warm, the lights may be taken off and the plants allowed to over-run the walls of the pit, and produce fruit in all directions. They should be well supplied with water, and have liquid manure occasionally. I am assuming that your correspondent has a warm house or pit at work in which to raise his plants. Besides Vegetable Marrows, with a number of pits and plenty of fermenting materials, very many other vegetables may be forced to supply an anticipated scarcity next spring. Early Potatoes may be had in quantity; Peas of the Tom Thumb section may be sown in pots early next month, and the pots set on a bed of leaves near the glass, both of which will be early and productive. French Beans may also be treated almost in a similar manner, only they will bear a few more degrees of heat than Peas. Cauliflower plants of medium and late sowings may be helped on now in pots near the glass, where a little heat can be given till they are quite strong, when they may be planted about 1 foot apart in one of the pits; as the space is too valuable to give much room, any deficiency in this respect must be made up by abundant supplies of liquid manure. Early French Horn Carrots may be sown from this time onwards. The white strap-leaved Stone Turnip may be had very early, and of better quality than can be obtained outside. Lettuce, Radishes, and small salading may likewise be had in abundance when space under glass can be spared. Seakale, Rhubarb, and Mushrooms also may be successfully forced in pits such as those described. E. HOBDAK.

Potatoes and Rotation of Crops.—Gardeners seldom think, I suppose, of planting the same quarter with Potatoes two years in succession, or it may be seldom once in three or four years. Perhaps it is not generally known, however, that ground will bear cropping with the Potato longer, year after year in succession, than with any other plant, before getting "sick" as it is called. Still one would hardly imagine that a piece of ground scarcely a spade deep would bear crops of Potatoes, and five crops too, year after year in succession, for nearly twenty years. Yet this, I believe, has been done, and not unfrequently. I am acquainted with one plot of ground, belonging to the superintendent of a national school, that has produced heavy crops of late Potatoes every year for ten years, to my knowledge, and it had been cropped in the same way for some years before I knew anything of it. This autumn I saw a fine crop of Paterson's Victoria taken off the piece as usual; and there seems no reason to believe that it will ever get "Potato sick" at any future time. The ground has never been trenched, and is not extravagantly manured—whatever manure is used, which is generally from the farm-yard, having to be paid for annually. "Facts are chiefs that winna ding;" and my friend the schoolmaster is inclined to be rather facetious when the rotation of crop theory is insisted upon in the face of his Potato crop, which is always equal to the best in the neighbourhood.—*The Gardener.*

Sulham Prize Celery.—Mr. Tegg, the gardener at Bearwood, who grows yearly a large quantity of Celery, only cultivates the Sulham Prize Pink, of which he exhibited at Reading the other day superb samples; not picked here and there, but taken from the row just as they come. He pronounces it to be the very best Celery he has ever grown.—D.

THE FLOWER GARDEN.

A WINTER FLOWERING HONEYSUCKLE.

(*LONICERA FRAGRANTISSIMA*.)

This is an extraordinarily sweet and useful Honeysuckle, well deserving the name *fragrantissima*. It flowers in the depth of winter—from December to February and March—a season during which it, of course, often encounters severe frosts. Instead of the flowers, however, being destroyed they continue to exhale so exquisite a fragrance that no garden should be without them. This shrub, unhurt by frost, will flourish in any soil or situation, and is, in short, one the cultivation of which we heartily recommend. It may be

The most fragrant of Honeysuckles.

raised from cuttings which generally strike well, whether in a green or ripe state. It is believed to be a native of China. A. B.

COLOURS OF FLOWERS AND INSECT FERTILISATION.

YOUR correspondent, "A. D." (p. 497) is, perhaps, not aware that plants, as regards their fertilisation, are divided into two classes, homomorphic or self-fertilising, and heteromorphic or cross-fertilised. All diclinous plants, those in which the sexes are divided, are necessarily in the latter class. These heteromorphic plants are sub-divided according to the way in which they are crossed, whether by means of wind, water (as in *Vallisneria*), birds, or insects. Some plants have two forms of flowers, one inconspicuous and self-fertilising, the other conspicuous and cross-fertilised. Following up Mr. Darwin's aphorism, "Nature abhors perpetual self-fertilisation," Prof. Hildebrand and others went too far in expecting universal crossing; yet the facts remain that, in many cases, crossing is absolutely necessary; in others it is facilitated by the structure of the flower and is beneficial to the production of seed; in others it is favoured by the prepotency of foreign pollen; and in a very few cases it is impossible. Wind-fertilised flowers have always an inconspicuous appearance, whilst those fertilised by insects are either scented or conspicuously coloured, but seldom both. Your correspondent seems to consider that we are only guessing, but the experiments of Mr. Darwin and the observations of Hermann Müller have established the above-mentioned principles on an incontrovertible basis of fact. No one denies the existence of self-fertilised forms, or the necessity of the intervention of insects in other cases, or the effectiveness of odour as an attraction to insects. The slight but distinct colour of the flowers of *Mignonette* would serve to direct insects previously attracted to the plant by its odour. I beg to submit that *Charlock* is as attractive; but, on the whole, not more common than the *Poppy*. Pollen certainly has no effect on distinct species; but, I think, insects do frequently confine their attention to a single species. The point at issue in the pages of *Nature* was not the necessity but the origin of brilliant colours. The Darwinian hypothesis is, that slight variations have been intensified by natural selection. The opposite view

is, that "beauty is an object in Nature." This expression I fail to comprehend, and can only say that it is no explanation. As Mr. Darwin says ("Origin of Species," chap. xv.), "it is so easy to hide our ignorance under such expressions as the 'plan of creation,' 'unity of design,' &c., and to think that we give an explanation when we only re-state a fact."

G. S. BOULGER.

S, Westbury Road, Harrow Road.

The Crimson Schizostylis (*S. coccinea*).—I beg to endorse all that your correspondent has said in praise of this plant; I, too, have a long row of it, which is, and has been, in fine condition for many weeks. I also grow it for greenhouse decoration in winter, and this year had it in flower till the latter part of February, with merely the protection of glass. My plan is, to divide the tufts in May, and plant them in rich and rather stiff soil in an open situation, watering them in dry weather. By the first week in September they make fine clumps, when I carefully lift them with a ball of earth, giving them plenty of pot room, and place them in a sunny situation until the approach of frost. They are then either moved to a frame or to a cold house, where they continue their bloom in long succession. It seems the more flowers are cut from it the more spikes the plant throws up. It is a plant for everybody, and all who possess a rod of flower garden should obtain it.—J. M., Hawkchurch, near Axminster, Devon.

Roses on their own Roots.—I do not see any reason why these should not become the rule, and budded ones the exception, as it is only exceptionally delicate sorts or those of a peculiar habit of growth that appear to be benefited by other roots than their own. In the case of standards every Rose grower sustains losses in the shape of heads blown off at the junction between stock and scion, and with Roses grown in that way there is always a difficulty in keeping down suckers, evils which would be avoided were they on their own roots. One or two good strong dwarf plants of each variety might be planted for stools, sufficiently far apart to admit of the shoots being layered all round; when rooted, these should be planted in nursery beds for a year. Those intended for potting or for dwarf beds should be cut down close to the ground in spring, and those intended for standards or pillars should be trained up to stakes. Roses on their own roots make equally good standards, and in as short time as budded ones, and no danger need be apprehended of their heads blowing off; besides, should they be killed to the ground by frost they will spring up again—a Rose instead of a Briar. The stems will not be so thick for the first few years as those of budded Roses, but they will increase in proportion to the growth of the head; and, as standards are usually supported by stakes, small stems form no drawbacks. We have some strong-growing varieties like *Charles Lawson*, *Charles Lefebvre*, &c., treated in this way that have surpassed in growth and general appearance Roses grown on the Briar.—J. Groom, Henham Hall, Suffolk.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Saxifraga longifolia as an edging.—This beautiful Saxifrage is grown by the thousand at Drumlaurig; edgings of it hundreds of yards in length may be found in connection with ribbon and mixed borders in the kitchen garden, and it is equally useful for edgings to beds, whether they are filled with *Geraniums*, *Alpines*, or herbaceous plants. It may be increased by means of offsets, which should be carefully taken off in autumn, and planted and wintered in a cold frame.—J. Muir.

How to Propagate *Diplopappus chrysophylla*.—In reply to Miss Hope's enquiry (see p. 497) as to the propagation of this plant, I may state, as the result of my experience, that when growing freely, and in about a half-ripened condition, the young shoots, taken off with a bit of beel, notched, as it were, out of the main stem, will strike freely, merely protected by a hand-glass, provided they receive the ordinary attention—a morning breath of fresh air for an hour or so. Bottom-heat, unless of the very mildest description, is ruinous to this plant; and stunted ill-conditioned plants will always result from using the hardwood such as is represented by the twiggy shoots covered with leaves.—J. C. NIVEN, *Botanic Garden, Hull*.

True Creepers.—Your correspondent "T." (p. 517) has made a comparison between root-creepers and "root-climbers" (see Darwin on "Climbing Plants.") There are hundreds of hardy root-creepers, but the number of hardy root-climbers is limited. We can add, however, to his list *Bridgesia spicata*, *Rhus radicans*, and *Enonymus japonicus variegatus*. I should add, also, the *Ephedra* (*distachya* and *monostachya*) and *Lygodium scandens*, but I add them doubtfully, as I have not got them in my garden to refer to. I have seen a Strawberry creep up a wall without assistance, rooting as it went; and the *Linaria Cymbalaria* is distinctly a climber, with the difference that it generally commences at the top of a wall, and climbs downwards, rooting as it goes.—H. N. ELLACOMBE, *Bilton Vicarage*.

Gravel Walks: J. T. R. The best material for surfacing is good yellow binding gravel, with the coarse stones removed. Burnt clay is more suitable for the substratum. The best walks we know of are those thus made in London gardens. When finished off with a sprinkling of sea shells (which soon become ground into small particles), as in the broad walk in the Botanic Gardens in the Regent's Park, and the broad walk in the Park itself, they surpass any walks we know of, and are almost as agreeable to the foot as a close carpet of turf.

THE FRUIT GARDEN.

THE GRAPE VINE.

Formation of the Vine Border.

THE Vine will thrive well in a very shallow soil, with ample supplies of water at the roots and frequent top dressings; but the results are more constant and enduring when the soil is deep. Besides, a uniform degree of heat and moisture at the roots is essential to the well-being of all plants, and to none more so than the Vine; and those conditions are better secured by a deep border than a shallow one, as, the greater the bulk of soil, the less liable is it to be influenced by external circumstances. Three feet of soil, on the average, is a suitable depth; which, with 9 in. of drainage, will make a total depth of 3 ft. 9 in. to the bottom of the border. A greater depth of border than this has been recommended, but to go beyond 4 ft. would, in my opinion, be only to incur additional expense to no purpose, and to render subsequent operations inconvenient. The width of the border must depend upon the size of the Vinery and the extent of training surface. For a house of the dimensions I have given in a former chapter, a border 25 ft. wide, including the inside portion, will be required eventually; for, though the inside border had better be completed at the beginning, it is not necessary to form the whole of the outside border at first, which may be completed by ekes added annually for the first two or three years after planting, as the roots are found to progress outwards. These additions give the Vines a fresh stimulus every year, and ensure a more even distribution of the roots throughout the border. When facilities for perfect drainage exist, the surface of the border need not be more than 1 ft. above the natural level of the ground at the front of the Vinery, and it may slope down to the ground line at its outer edge. The Vine is a grosser feeder and a greater drinker than many suppose, and more failures have probably resulted through borders being made too high than too low. Operations commence by first marking out the area of the border, and then removing the soil and sub-soil to the required depth, taking care that the bottom has an even slope to its outer edge when finished. When new Vineries are to be erected, this work is done when the foundations are taken out. At this stage, also, the bottom heat, if it is to be secured by aeration or hot-water pipes, must be seen to as directed in a former chapter. Here I am speaking as if no such means were employed.

Sub-soil Drainage.

In some situations the sub-soil is so dry, that its drainage is neither necessary nor desirable; in others, a single drain 3 feet deep, carried round the ends and along the front of the border, is sufficient; while, in cases where the sub-soil is wet, or the rainfall excessive, the drainage becomes a matter of the first importance. In the latter case, a drain 3 feet deep, having a good fall and a ready outlet, should be carried along the front of the border, and, into this, drains driven across the border from back to front, and 8 or 10 feet apart, should be led in such a manner as to prevent the possibility of water stagnating about the roots or in their vicinity. On the bottoms of the drains 3-inch tiles must be laid, and the drains filled up with broken stones to the top. After this, the concreting of the bottom must be considered. When the sub-soil is rocky, or of a hard and dry texture, concreting is unnecessary, for the roots of the Vine rarely penetrate such soils—at least, I have never found them to do so, even in the case of Vines planted fifty years or more; but they are pretty certain, sooner or later, to find their way into a soft spongy soil in quest of moisture, and concreting is then the only preventive. An easy and effectual enough way of doing this is to put a layer of rubble about 4 feet deep on the bottom of the border, in order to form a dry bottom; upon the top of this another layer of equal thickness, composed of smaller stones, broken bricks, or clinkers is laid; and over this, again, a layer of lime, or lime and sand, of sufficient consistency to cement the materials together and form a good crust, is spread, and the whole rolled or beaten and left to set. If this work is done well—and masons' labourers are the best hands at it—there will be no danger of the roots getting into the sub-soil. As soon as the concrete is hard enough to permit of further operations, 9 inches of drainage, consisting

of brickbats or stones, should be laid on it, keeping the largest stones on the bottom, and reserving the siftings for the top. Above all a layer of sods, grassy sides downwards, should be laid, to prevent the soil from being washed in amongst the drainage, and the border is ready for receiving the soil.

Soil for the Vine.

It has long been supposed that the Vine preferred a calcareous soil to all others, which has led to an extravagant use of lime in the formation of Vine borders; but more recent experience has shown that it will thrive quite as well, if not better, upon the red sandstone, and in deep and strong loams. All of which simply goes to prove that the Vine is cosmopolitan in this respect, and adapted by Nature to thrive under very different conditions as regards soil; hence its wide distribution. It has its proclivities, no doubt, and these should be studied when opportunity offers; but it should also be known, for the sake of that numerous class who have but small facilities in that way, that the Vine will thrive well in any soil that will produce fair crops of Peas and Potatoes, or other vegetables, provided it is as liberally treated as these generally are. Another prevailing notion is that the soil for a Vine border cannot be too open in texture, and to maintain the border in as porous a condition as possible has hitherto been the aim of many Grape growers; but this notion is fallacious—for, though a border composed of chopped turf is the best to begin with, as the Vines root into such material quickly and get a grasp of the border at once, it is not by any means necessary to keep up this spongy texture, for a hard soil seems as congenial to the Vine as any others. When a Vine is hard potted it invariably makes the most roots and a good cane, and it is the same in a hard border; the roots do not travel so far, but they are far more numerous—in fact, obstruction has exactly the same effect as root-pruning, which has been practised on young Vines with the very object of keeping the roots at home, as the phrase goes. I grow many pot Vines here every year, and have compared those which had their roots cut several times before being put into their fruiting pots, with plants grown in the usual way but firmly potted, and never found any difference either in the crops or the appearance of the roots afterwards. My opinion, founded upon observation and considerable experience, is that what is generally denominated a "strong loam," of a solid texture, is the best for sustaining the Vine in vigour and fertility for a long period; and from choice I would prefer the top spit of a heavy pasture land to any other for border making. From such a soil constant and heavy crops and large berries may be confidently expected, and the least shanking, if any. The soil here is of an unusually heavy character, and borders composed of turf originally soon settle into a solid mass; but Vines thrive long and well in it, as the following instances will show. Up till three years ago we had a house of Vines, Black Hamburgs, which had been growing in the same border for sixty or seventy years, and which, so far as I could learn, had always borne good crops of Grapes. The border, which was outside, and about 3 feet deep and 16 feet wide, was composed entirely of this heavy loam, apparently without any admixture, and had long ago become a hardened mass. About twelve years ago a new Vinery was built over the old Vines, it being considered preferable to keep them on to planting young ones. The new Vinery, being larger, permitted their further extension, which improved them considerably, and for the remainder of the time—eleven years—they were forced for a second early crop, and always bore fine fruit. When it became necessary to do away with these Vines in order to extend our late Vinery, I had the curiosity to examine the condition of the border and the state of the roots. After removing the soil—which had accumulated in the course of years to a depth of 15 inches or so, and which contained no roots at all—I came upon the original yellow loam of the border, and found it to be permeated in all directions with roots of the most healthy description, which explained the long-sustained vigour of the Vines; but I confess the soil, both in quality and texture, was not such as I had at one time regarded as favourable to the Vine, for it was stiff and tenacious, almost approaching to clay. We have another Vinery here—a ridge-and-furrow—50 feet long and 6 feet wide, with a restricted

training area, containing four Vines, which annually bear close upon 400 lb. weight of Grapes every year, and the berries (Hamburghs) are seldom under an inch in diameter on the average. These Vines are growing in an unprepared border, about 3½ feet deep, of the same stiff loam; and, though the roots are all outside, and only protected in winter by a mulching, they are always to be found in a state of good health. A hard soil is the driest of all soils, according to my experience. These and other instances of the same kind have led me to prefer a strong loam to all others for the Vine; and if it is a sandy loam, so much the better. There is no doubt, however, that lasting results can be obtained from light loams as well, but they require more feeding and attention. The old Vines at Cole Orton Hall afford a remarkable example of successful culture in this respect. Mr. Henderson has had charge of the gardens there for thirty-five years, and it is well known that during that time he has been one of the foremost exhibitors at our great shows—his examples as a rule fairly representing the crops produced annually for his employer's table. Mr. Henderson disclaims being a sensational Grape-grower, rightly measuring success by its continuance, neither is he a believer in expensively formed Vine borders, having proved by long experience that the best results can be obtained by simple means intelligently applied. Information regarding the Vines and borders at Cole Orton will doubtless be acceptable and instructive, and, through the courtesy of Mr. Henderson, I am able to give it in his own words. He says: "The principal Vine borders here were made before I came to this place in 1838, and the Vines have been planted forty-three years. I do not attribute the excellence of the Grapes altogether to the materials of which the borders consist, but to the constant drawing of the Vine roots to the surface by means of manure put on the borders, about a foot thick, every year, thereby raising a gentle heat. Our soil is rather a light loam on the red sandstone formation, and the only Vine borders I have made here were made of this loam, with the addition of one-twelfth of good stable manure. No other materials were used, and the Vines planted in this have always been the best Grapes. The borders were only made 7 feet wide and 18 inches deep, and the Vines have been bearing for thirty-four years." Such is the simple story of one of the most successful Grape growers in this country. I am acquainted with another exactly parallel case. In a little Vinery belonging to a country clergyman with whom I am acquainted, crops of high excellence have been produced for twenty years. The minister is an enthusiast in Grape-growing, and attributes his success to that, and heavy waterings, mulchings, and liberal manuring. The border was originally composed principally of the garden soil, trenched over and manured. Mr. Coleman, of Eastnor Castle—who also produces excellent crops of Grapes from aged Vines—attributes his success to the use of a moderately heavy loam from the volcanic formation in his neighbourhood, which, he says, does not retain its fibre long, but nevertheless induces a profusion of healthy roots, such as the calcareous loam, which he has also tried, never does. Mr. Coleman was led to try this soil from observing that fruit and other trees grew well in it—not a bad way of guessing at the quality of the soil at any time. Gardeners have generally to choose soil from their own locality, and they will not err far if they always select the top spit from localities where the Oak, Ash, Lime, or Sycamore are observed to thrive well. The turf should be taken off the ground when it is moderately dry; and if it cannot be prepared and put into the border at once it should be stored in a dry shed, and there chopped up with the spade. If the soil is of an unusually heavy texture, one-third of decayed and rotted manure and river sand may be added to it to lighten it; and in all cases a considerable quantity of broken bones and bone-dust should be used, and in non-calcareous soils about the same quantity of lime scraps. The whole should then be turned over and mixed several times, and left till wanted. If the borders can be got in readiness for the reception of the soil a month or two before planting time, so much the better, as it gets time to settle, and there is less danger from fermentation, which often occurs with fresh turf. In cases where the means for forming Vine borders as here directed are not available, the site may be drained without removing the natural soil if it is an ordinary fair sample; and

after doing this, the ground should be trenched over 2 or 3 feet deep according to circumstances, adding at the same time a good sprinkling of broken bones and well-rotted cow-dung or stable manure, mixing the whole together as the trenching proceeds, and taking care at the same time to level the surface of the sub-soil in a regular way as each trench is turned over, and to ram it well with wooden rammers if it is of a soft texture, to prevent the roots from getting down into it.

(To be continued.)

AMERICAN RED RASPBERRIES.

At last our fruit growers are beginning to appreciate our native Red Raspberry. For a century we have been importing or raising varieties from the European *Rubus idaeus*, and neglecting our hardy and excellent native *Rubus strigosus*, or common Red Raspberry, which is found almost everywhere, from Hudson's Bay in British America to the Gulf of Mexico. Of course, among the vast number of plants growing wild there are many natural varieties, and it would be indeed strange if some were not worthy of cultivation. It is true that an occasional variety was tried, but the foreign sorts being, as a rule, larger and to some persons of a more agreeable flavour, the native wildings were neglected, few or no attempts having been made until quite lately to improve them. Then, again, those who had inclination and leisure for trying experiments in this direction appeared to overlook all other merits besides that of size and flavour, consequently they procured seed from the large foreign varieties instead of from our more hardy native species. The results are well known, and we can show plenty of seedlings of the tender foreign species which are equal in every respect to anything raised abroad. The Clarke, Brinckle's Orange, and President French are certainly good enough in every respect except hardiness of the plants. After making what appeared to be rapid progress for several years in the culture of this fruit, there seems to be, of late, an inclination on the part of its cultivators to go back to the native wildings and produce a new and more hardy race of varieties therefrom. This was the point from which our pomologists should have started in the beginning; but as we looked to foreign countries for all other kinds of fruits, why not the Raspberry?

Cause of the Change.

The increase in our population and in the number of cities and villages caused an increased demand for fruits, and experience with the foreign varieties has shown that they do not succeed except in every circumscribed localities. The Red Antwerp, which is the variety most popular for cultivation on the banks of the Hudson, is scarcely cultivated elsewhere, for the very good reason that it seldom succeeds outside of the region named, and even there great care is required in giving protection in winter. The bending down the canes in autumn and covering with earth, is not a very expensive operation, still it is an irksome task which cultivators will avoid whenever possible. Other sorts of the same parentage are also tender to a greater or less extent, hence the desire to produce more hardy sorts and get rid of the expense of giving protection in winter. In addition to the hardy character of our purely native sorts, it has long been known that they will thrive in a greater variety of soils as well over a far wider range of country, than those produced from the foreign species.

Too Many Suckers.

One principal objection urged against one of our native varieties, *R. strigosus*, is this peculiar habit of producing a great number of suckers from the subterranean stems and roots. If these suckers are allowed to grow without a check through the summer, they are likely to rob the main stool of the requisite amount of nutriment necessary to produce good strong fruitful canes. In other words, the strength of the plant becomes too widely distributed to ensure productiveness; but this may be readily avoided by hoeing off once or twice in the season, as we are obliged to do with the weeds. It is no more trouble to keep down suckers than weeds, and the operation may be performed at the same time without any additional expense; but if weeding and removal of the suckers on their first appearance are neglected, a plantation of even the best sorts will soon be ruined.

Promising Varieties.

The Wilmington, Kitland, Pearl, and several other purely native sorts have all been thoroughly tested, and promise well for general cultivation wherever the Raspberry is known to succeed. But there have been very few experiments made in the way of raising new sorts of our native Raspberries from seed; therefore there is a rare

opportunity for those who feel so inclined to produce varieties of great value. Every fruit grower can afford to try, even should he not succeed in making any great advance upon the older sorts; but the one who draws, so to speak, the lucky number is certain to be well repaid for his labour.

The above, written by a correspondent of *Moore's Rural*, whose knowledge of gardening subjects is extensive, reminds us of our neglect of the varieties of American Raspberry, which are sufficiently hardy for cultivation in England. We have seen with Mr. Tillery, and in Mr. Peake's garden at Wimbledon, excellent results from American Blackberries; and there is, in addition to these, various other important small fruits which well deserve a trial in our gardens, and would probably add agreeable variety to the dessert. The subject would seem to be more worthy of the attention of the Royal Horticultural Society than repetitions of trials of the same classes of plants year after year in succession.

CULTURE OF POT VINES.

THE time of year will soon arrive when we ought to be making some preparations, if we mean to cultivate Vines in pots, which are seldom grown with great success, though if managed in the following manner their culture is simple, but of course requires attention. The first step will be to select some nice strong well-ripened eyes of the Black Hamburgh, and I do not think you can do better than strike a few eyes of Foster's White Seedling, so as to have a variety. As yet I have found no white Grape to equal it, that is, for pot culture; of course there is ample time yet to secure what I call first-class pot Vines, as I never doubt success if I can only get them into a nice brisk heat in the month of February—not later. My system of growing them is as follows:—I procure some nice rich loam and one-third leaf mould, inserting each eye singly into thumb-pots; then plunge them in some nice bottom heat, and if they are well ripened eyes they will soon move. At this stage the compost will be required more rough than before; one-third charcoal is a good help, as it will keep the loam light and open. When this compost is all ready, and you have obtained a sufficient quantity of 6-inch pots, all clean and carefully crooked, sprinkle a little soot over the crooks, to keep out worms and also to feed the Vines. I find they do much better than they otherwise would do if a little soot is used; then, if they are nicely rooted, pot them on into the pots mentioned, placing them again in the same bed as before until they are nicely started. The compartment I grow them in is a common Cucumber pit, with the hot-bed made of dung, just the same as you would use for Cucumbers; the pit should be 16 feet long; plunge the pots into it at one end, then train the canes horizontally along the pit. After they have received the last shift, which will be into 14-inch pots, plunge them again into the same pit, there to remain until they reach the extreme end of it. In potting them the last time use about a third brick-rubbish, not forgetting the soot as before mentioned; the dung ought to be 18 inches from the glass, and then all the training that is required is a peg to keep the leaders down; when they have reached the end of the pit, harden them off by degrees until you can take the lights off altogether for a few days; then, taking the Vines out, replace the lights, placing the pots containing the Vines outside, in the front of the pits; then lay the canes on the outside of the glass, as in this way they will ripen best, and, what is more, you get good fruiting canes in one year—in fact, I consider them far better than canes two or three years old. Pot Vines, if plunged in the way mentioned require but little water and also little attention, but a free supply of air should be given whenever the weather will permit.

G. M. A.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Pear Synonyms.—You were not quite right when referring to the *Fondante du Pays* (p. 457) to speak of the *Passe Colmar*. As a synonym of *L'Orpheline d'Englheim*, *Beurre d'Arenberg* Belge should have appeared, and *Arenberg*, not *Arenberg*, should have been printed. *Glen Moreau* is not the synonym of the *Colmar d'Hiver*, but is a name justly applied to the *Beurre d'Hardenpont*; the *Bertramotte Fortune* was raised by Parmentier.—F. J.

Marie Louise Pear.—In the notice of the Royal Horticultural (of Ireland) Society's winter show of fruits, held at the Rotundo last week, the *Irish Farmers' Gazette* remarks that in the class for the best dish of any variety of dessert, first, second, and third prizes were won by Marie Louise, which, when in good condition, has scarcely yet a rival. The Liverpool show of fruits was held almost on the same date, and the result was the same, Marie Louise being there also credited with first, second, and third prizes.

New Variety of Pine-apple.—I observe, in M. Linden's catalogue of stove and greenhouse plants for 1874, *Ananassa Mordilona* described as follows:—"A delicious new variety of Pine-apple, from the cool regions of Colombia. The fruit attains a weight of 12 lbs., is of an exquisite flavour, and of a beautiful violet colour. The native name is *Mordilona*." This species, if the description is a fair one, would appear to be very desirable. Have any of your correspondents tried it? Is it as good as it is described?—N. T. C. R.

THE TUILERIES GARDENS.

AMID all the strife of parties, and notwithstanding the many vicissitudes of France, the public gardens of Paris remain uninjured, and even improve from year to year, at least, so far as permanent planting is concerned. It is true that the misfortunes of the country have cut short the large supplies that were so freely given for city gardening before the war, but it is, nevertheless, surprising to see how much attention is still bestowed on the public gardens. In saying a few words on the condition of the Tuileries Gardens in their best days (before the late war), we shall only allude to matters of some interest to all lovers of gardening, and not from the point of view of public gardening only. The most noticeable fact among the permanent plantations was the abundance of shrubs, flowering and otherwise, which were trained to attain their full perfection, or rather were allowed to attain it. Sufficient space for each plant to stand in grow secured for it fine development. There was none of that close-crowding, which is the rule in shrubberies generally; and, in consequence of which, most of our shrubs are merely effective in composing thickets by no means ornamental. This care for the individual shrub or low tree, as the case might be, was carried as far as the regular thinning of the branchlets of flowering shrubs, like the Lilac, so as to secure a well-formed tree and a stronger bloom. Stiff as the garden is, in consequence mainly of its wide straight walks cutting up all the great central spaces, it owes none of this stiffness to mere formal arrangements of plants, to elaborate geometrical display of beds, or to coloured gravels and the like. Vegetation, as in any Italian garden, which produces a good impression, predominates and relieves the effect of the statuary or stonework introduced. There is an abundance of verdure offered by richly-grown copings of Irish Ivy, and there are mixed borders of effective plants along most of the walks, while the squares have open carpets of well-kept turf in the central parts. The mixed borders include Lilac bushes, dwarfed by close annual cutting, Cannas, Roses, Honeysuckles, and well-chosen herbaceous plants. In autumn they are planted with spring flowers which blossom on till about the time of Lilac bloom, when the summer occupants replace them. The practice of relieving the stony glare from pedestals, statues, &c., by rich bands of Ivy and graceful mixed borders, as shown in the illustration, produces very happy results. Indeed, such garden-embellishments are only pleasing when carefully treated in this way, and, notwithstanding the means taken to tone them down, there were too many huge vases, statues, &c., in these gardens to permit of that repose which is the greatest charm of a garden. The Orange trees here are very fine, and form a costly relic of times when hardy evergreens were not so plentiful as they now-a-days are.

The London Fruits and Flowers of the Olden Time.

—These were celebrated for their fine quality and beauty; Shakespeare alludes to the fine Strawberries, for which the Bishop's gardens at Ely Place were celebrated; though the dingy mass of brick buildings by which what was then an open space is now covered, would lead few to surmise, when passing through that smoky region, that they are walking over what were once luxuriant Strawberry beds. The neighbouring Hatton Garden, betrays, by its name, that there was once beauty, where now ugliness reigns supreme; while many back "slums," more hideous still, retain the name of gardens, though in their parlous the very rankest weed could not now be persuaded to grow in the soot and filth poisoned soil. In Bath Street, Bethnal Green, where there is no longer either bath, or pond, or green, a nurseryman bearing the glorious name of John Milton, once raised fruit and flowers, which were celebrated for their excellence, and were sought for far and wide, all over the country. But the spot is now all filth and squalor; out of which, however, recent improvements are fast raising it, which is encouraging. It is moreover satisfactory to know that by "aiding Nature," as Shakespeare has it, both fruit and flowers may still be raised in London. The cheap rate at which sheets of glass may be made to intervene between the poisoned elements and natural vegetation, acting as a shield to ward off both smoke, and smoke-infected rain, renders its application available to almost any extent. Every house, indeed, may have a crystal-covered garden on its roof; as shown by the elegant terminal structure of glass which surmounts the handsome premises just completed by Mr. Burr, in King Street, Covent Garden.

THE PRIVATE GARDEN AT THE TUILERIES IN 1870.

GARDENING FOR THE WEEK. AND AMATEUR'S CALENDAR.

Roses.

IN visiting small gardens near London I have noticed the attempts of many to grow a Rose tree in their little plots of ground, and their great disappointment at not being able to obtain a single flower from their Rose bush, as it may be termed, for it is seldom more than a common green bush, being either the common Provence or old Damask variety of Rose, of which they have been able to obtain a small plant. Notwithstanding all they do, and the more they nurse and cherish it, to their great disappointment it does not flower. As Roses are so cheap, and can be obtained from any of our Rose growers from 12s. to 30s. per dozen, or from 1s. 6d. to 2s. the single plant, I would advise those who have Rose trees planted, and have met with the disappointment above mentioned, to have them all pulled out and plant Roses worked on the Briar stock. I recommend the Briar because if it once take root in any soil it is almost sure to grow. Disappointments are occasionally met with in planting the Briar, but they are rare. The Briar stock is found in marshy places, as well as in the driest banks, flourishing in hedgerows, and by obtaining a few horse droppings, and mixing them with the London soils, where fresh loam is dear, and, in fact, scarcely obtainable, the Briar will be found fully to succeed. In selecting the varieties, it is always as well to tell the Rose grower the kind of situation you wish to plant with Rose trees, and he will select for you the most suitable varieties. The two great points required are free-growing and free-flowering varieties, such as Hybrid Perpetuals, or Teas, if of the Gloire de Dijon constitution. There is plenty of time for planting Roses till March; although planting is generally recommended for November, I have seen Roses cut off plants for exhibition that have been moved by nurserymen very late in the season. The great thing to look after in late planting is to well water the plant, and if we get dry frosty east winds, to give the late-planted Rose tree some slight protection, so as to keep the wood from shrivelling; and, if this be found to be the case, syringe the bark occasionally—say every morning—so as to thoroughly damp the tree all over, and it will soon be found that the tree has commenced to make root. The bark will soon fill up plump and solid, and the buds will look prominent. If the Rose trees have been some time out of ground before reaching their destination, I would advise planters to make a puddle of earth and water nearly, or quite, as thick as paint, dip the roots into it, so as to give them a thorough coating over, and plant directly. It is only advisable to use this puddle in case the roots are thoroughly dried up. Some growers recommend it always, but in good soils it is not required. I have seen the turf plot covered with standard Roses in some of the villa gardens round London, and, however much such formality may be deprecated, the variation of colour had a much prettier effect than is produced by unsuccessful attempts to grow scarlet Geraniums and plants of a similar character.—G.

Flower Garden and Pleasure Grounds.

IN many instances the Oak and a few other trees have this season retained their leaves to a later period than is usually the case, a circumstance which may be attributed to the destruction of their first growth by the frosts which occurred during last May. The frosts, however, which have been recently experienced, have had the effect of bringing all, or nearly all, of them to the ground; and if not already cleared off lawns and walks, &c., this should now receive immediate attention. The leaves should be stored in situations as near as possible to where they are likely to be required, with a view to forming hot-beds and for other purposes. Stakes, ready prepared for supporting plants in flower beds, as well as in pots, can be purchased at a very reasonable rate, but, where this is not done, they may be made of deal laths, split, and cut into the various lengths likely to be required, and neatly smoothed by means of the knife. They should then have a coat or two of dark green paint, to render them as little conspicuous as possible; and the ends intended to be inserted in the soil, may, with a view to their preservation, be dipped in hot pitch. In supporting plants in flower-beds on the lawns, or elsewhere, it is of importance to conceal, as much as possible, the stake or stakes used for that purpose; but, unfortunately for the general effect, this circumstance does not always obtain the attention which it demands. Very suitable stakes for out-of-door purposes may also be made from the straight shoots of one or two years' growth, produced by stools of Hazel, Elm, &c., also the small straight twigs of the common Snowberry, and in all cases allowing the bark to remain on. It is also advisable to avoid the use of stakes formed of the shoots or branches of such trees as the Poplar and the Willow, which are almost sure to strike root and rob the plants they are intended to support. Pegs for the purpose

of fastening down Verbenas and similar plants, may also be prepared now, and may be made of Birch or the trimmings of sundry other trees, and the making of which will furnish profitable employment during cold and unfavourable weather. For the purpose of naming specimens of ornamental trees and shrubs on lawns, &c., elegantly designed metallic labels can be cheaply purchased from any nurseryman, made to be inserted in the soil, or to be attached to the plants, and of various patterns; but wood labels suited to the purpose of naming and numbering bedding plants in pots can be readily made from selected deal laths, which will only require to be rubbed over with white paint, when about to be written upon. Beds of late planted Pinks and Pansies are not unlikely to become uprooted by worms, or to become loose in the soil, and will require to be occasionally looked to, and to have the soil pressed gently round them and the Tulip beds may, with advantage, have a covering of old tan or leaf soil. Auriculas and other Alpine plants in frames, should have abundance of air during fine days, and should be frequently examined after dark with candle and lantern, as slugs are likely to attack them about this time, to prevent which a little quick lime or soot should be occasionally sprinkled among the pots. Give abundance of air, during fine days, to the hardier kinds of bedding plants, when they are thoroughly rooted. Scrubby Calceolarias of all sorts, Verbenas, *Koniga variegata*, *Leucophyton Brownii*; the latter, one of the neatest of all silver-edging plants, will all be perfectly safe in a cold pit or frame, well matted up during severe frost. Ordinary greenhouse temperature will suit *Pelargoniums*, *Petunias*, &c.; while store-pots of *Alternantheras*, *Coleus*, *Impatiens*, and the very useful and pretty dwarf *Ageratum*, *Imperial Dwarf*, which is more tender than its tall-growing congener, should occupy a shelf, or similar position, near to the glass, and in a night temperature not much under 50°.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Hardy Fruit.

IN many gardens bush fruits do not receive the attention which they deserve; hardly anything grown in a garden affords more pleasure or is of more use in the arrangements of households than an abundant supply of good Gooseberries, Currants, and Raspberries; and yet they are often met with in out-of-the-way places and in poor condition even in the best gardens. They, however, are worthy of a piece of the best ground, the richest feeding, and the highest cultivation. Now is the time to see to the latter, either by forming new plantations or renewing old ones; the former is generally the most satisfactory course to adopt. It is, however, absolutely necessary for a continuous supply not to do away with old bush fruits until the new are thoroughly established and well grown into a fruiting state. The most efficient mode of renovating old fruit quarters is to prune in the old plants somewhat severely, rub off the Moss or Lichen from their stems, paint the whole overhead with a paint formed of quick lime, soot, and cow-dung—at once cleansing, nourishing, and protecting; then remove the exhausted soil down to the roots, clear it away, and replace it entirely with manure (if enough can be had) or a half-and-half of good stiff loam and manure, a foot or so thick. If the ground is found dry, soak it through several times, during the winter months, with house-sewage, slops, and soap-suds, all of which are capital stimulants for bush fruits. In forming fruit plantations, trench the ground 3 feet deep, incorporating at least 1 foot of strong farm-yard manure with the earth in the process of trenching. If the soil is light, cow and pig manure will be the best for this purpose. Plant the bushes at any convenient distance apart, from 3 to 6 or more feet, according to the intention to crop or not, between the bushes, with vegetables, the mode of training, size of garden, &c. Rows 5 or 6 feet apart, and 4 or 5 feet between the plants, are good distances. Bush fruits also form nice furniture for the base of walls or for espalier rails, and make striking pyramids. Of course the latter remark does not apply to Raspberries, which are generally planted in rows from 4 to 6 feet apart, the stools being 1 yard or 4 feet from each other in the rows. Raspberries also furnish and fruit well on strained wire or espalier rails. As to varieties of bush fruits they are very numerous, and almost each cultivator has his favourite sorts. The following are generally useful and good alike for eating and preserving, viz., *Rough Red Warrington*, *Red Champagne*, *Ironmonger*, *White Champagne*, *Bright's Venus*, *Early White*, *White Crystal*, *Yellow Champagne*, *Sulphur*, *Gold-finder*, *Early Green*, *Green Glenton*, *Green Gascoigne*, and *Pitmaston Greengage*. A few of the most useful of the larger sorts in each colour are *red*, *London*, *Slaughterman*, *Crown Bob*, *Roaring Lion*; *white*, *Antagonist*, *Snowdrop*, *Freedom*, *London City*; *yellow*, *Catherine*, *Broom Girl*, *Leveller*, *Trumpeter*; *green*, *Trumpeter*, *Jolly Angler*, *Turnout*, *Queen Victoria*. Currants, *red*, *Cherry*, *Champagne*, *Dutch*, *Raby-Castle*, *Knight's Sweet Red*, *La Fertile*; Currants, *white*, *Dutch* and *Cut-leaved*; *black*, *Black Naples*, *Carter's Prolific*, *Ogden's Black*, *Lee's Prolific*. Raspberries, *Carter's*

Prolific, Barnet, Victoria, Fastolf; Red and Yellow Antwerp, October Yellow, October Red, and Black. The best time to plant is November, but bush fruit may still be planted up to the end of the year.—D. T. Fish.

Orchard-house.

Great care must now be taken to protect trees in pots from possible injury by frost. Place them close together, and cover the pots with plenty of straw or Fern; Barley straw, on account of its flexibility, will be closer than Wheat straw, and, if it can be obtained, should be used in preference to that kind. Give no water until the severity of the frost has abated.—R.

Trees and Shrubs.

No time should be lost in preparing and trenching ground for planting deciduous trees and shrubs. Where it is intended to make large plantations and to plant thickly, the whole of the ground should be trenched deeply; but the sub-soil should not be brought to the surface, as plants do not often start freely in soil that has not been previously exposed to the sweetening influence of sun and air. In trenching, a good wide opening should be made, and the soil carted and laid in a ridge ready to fill in where the work finishes. Take the top spit off the next trench and remove in like manner, and the top soil of the next then comes right to lay on the surface, and so on all through the piece. If single specimens are to be planted, or the plants are to be placed far apart, it will only be necessary to dig large holes before planting, and the larger these are made the better, so as to thoroughly break up and loosen the soil, to allow the roots to ramify and get below in search of moisture. It is impossible for a plant to make satisfactory progress if this be not attended to, as it is difficult for the roots to penetrate beyond the limits afforded by digging a small hole. In planting, the roots should be carefully spread out and covered with fine earth, and when the hole is partly filled up, it is a good practice to well wash the earth into all the interstices of the ball by giving a copious watering, as it frequently occurs that large cavities are left under and about the ball if this practice is not resorted to. If the hole be then filled up without any further watering, and the surface well mulched, as it always should be, very few failures in planting will occur, as the mulching will stop the escape of moisture and prevent frost penetrating to the roots. After planting, every tree or shrub of any size should receive proper support to prevent them swaying to and fro, as it is impossible for root action to go on if they are constantly moving. In most cases one good stake, if properly placed, is sufficient. It should be placed in an opposite direction to that of the prevailing winds, which may affect the tree; but for large specimens it is necessary to have supports placed triangularly, taking care that they are not allowed to chafe or injure the bark of the tree, and by placing a good whisp of hay where the supports touch this may be avoided. I have been thus prolix in my remarks, as planting should be pushed on at this season; for the earlier it is accomplished the less labour and attention will the plants require to get established. It may be well to enumerate some of the most striking deciduous trees suitable for planting for ornament in conspicuous places. The Tulip tree (*Liriodendron tulipifera*), stands out almost unrivalled for its unique beauty, free growth, and gigantic stature. In addition to the ornamental character of its peculiarly cut leaves, it presents autumnal tints of the richest description, varying from the darkest mahogany to the richest claret, and its singular flowers add an additional charm. *Ailantus glandulosa* is a tree of majestic beauty and tropical appearance, fast growing, and not at all fastidious as to soil. It should have a place in every collection, as its distinct type of vegetation cannot fail to command admiration. The *Ailantus* is not suitable for very exposed situations, as the wood is not strong, and the tree is apt to be broken about by the wind. Many of the Birch tribe are valuable for ornamental planting, and have a distinctness of character quite their own, the pendulous varieties weeping down in the most graceful manner, while others are admired for the peculiarity of their bark. For ornamental planting the *Acers* should not be lost sight of, as they are amongst the most beautiful of deciduous trees of medium growth, both on account of their singularly cut leaves and the beautiful colours many of them assume either in spring or autumn. The young leaves of *A. japonicum polymorphum* are a beautiful scarlet when they first show, changing to a purplish colour which they retain to the autumn. *A. Colchicum rubrum* has leaves of a rich shining ruby and purple, and in hot dry seasons these colours are beautifully brought out. *A. fraxinifolium albo-variegatum* has beautiful green and silvery leaves; and, if planted in warm sheltered situations, backed by any dark-leaved plants, such as Yew or Holly, it is most effective. It is quite deserving a place in any conservatory, and is unsurpassed as a variegated decorative plant, as the leaves become very much larger than they are ever seen out-of-doors, and the variegation is much more pure and delicate. This and *japonicum*

polymorphum should be planted in sheltered situations; for, although perfectly hardy, they make their young growth early, and this is apt to be injured.—J. SHEPPARD, *Woolverstone Park*.

Kitchen Garden.

In the absence of evaporating pans or hot-water pipes, maintain a moist atmosphere in Mushroom-houses by means of syringing the walls and paths, but avoid over-watering the beds. A steady temperature of about 60 will be quite high enough at this season. In removing exhausted beds, any flaky pieces of spawn that show signs of vitality should be saved, in order to assist in spawning the new bed. An old friend of mine—a very successful Mushroom grower—used to spawn all his beds in this way. Very many of the failures in Mushroom culture arise from using old and inferior spawn. A thin covering of hay, that has been beaten with a stick to clear it of seeds and dust, should be placed over newly-made beds, and those in bearing also, for the double purpose of checking evaporation and for maintaining a steady heat. If woodlice are troublesome, pour boiling water round the edges of the beds close to the walls, after they have retired to their hiding places. Take advantage of frosty weather to get all wheeling done, so as to avoid injuring the paths. Few things are more conducive to cleanliness in a kitchen garden than a sufficient number of strong serviceable scrapers placed at the most convenient places for going on and off every border and quarter in the garden. A cheap kind of scraper suitable for such purposes may be made by any blacksmith. It consists simply of a piece of iron in the form of a T, the perpendicular portion being driven half-way into a stump of wood inserted 18 inches into the ground in order to keep all firm and steady. Take advantage of bad weather, when other operations come to a standstill, to make a lot of strong labels for labelling seeds and plants in spring. Whenever ice of sufficient thickness can be obtained, ice-houses should be filled without delay. Some recommend salt to be scattered amongst the ice in the well; others, again, advise water to be poured over it, in order to assist in congealing the ice into a solid mass; but I cannot say that I have ever seen any advantage to result from the adoption of either plan. The great thing is to have the ice thoroughly broken, and afterwards well rammed in the well; if this be properly done, there need be no fear about the result. By laying down a platform of planks at the entrance of the house, on a level with the sill, so that the carts can be backed up to shoot the ice upon the platform, the work of breaking will be better and more expeditiously done than it otherwise could be. A temporary platform of this kind can easily be made by laying planks side by side, with a stout piece of timber for the carts to back against, with two or three bundles of straw at each end. The first load of ice broken upon it will fill up all cracks and render the platform firm and solid. Where there is no ice-house a large stack may be made in the open air; and even where an ice-house exists, if large quantities of ice are required, it may be advisable, if ice can be easily obtained, to build a stack outside. It should be built on sloping ground for the sake of perfect drainage, on the north side of a belt of trees or plantation, where it is shaded from the mid-day sun. Having selected the site and decided upon its size, make holes with a crow-bar 18 inches apart all round, except just at the mouth or entrance, which should be left 3 feet wide. Into these holes insert stout poles, about 6 or 8 feet long, and let them be driven in firmly, then lace Ash or Hazel rods all round, not necessarily close together, but sufficiently near to keep up the straw inside in which the ice is packed. A good thickness of straw must be used, in order to keep all air-tight, and the whole, when completed, should be thatched in closely and thickly. Dry leaves form an excellent covering to heap over all, and a thin coating of straw over those again will keep them together.—E. HOBDAV.

Cottagers' Gardens.

All vacant portions of vegetable ground should now be deeply dug, or, if possible, trenched, and the earlier this kind of work is done in winter the better will the soil be for cropping in spring. Finish the planting of fruit trees as soon as possible, and give such as have been moved a good mulching of partly decayed manure, an application which will also benefit Strawberry and Raspberry beds. Prune standard and dwarf fruit-trees, except in places where the birds are liable to be attacked by birds, when the later pruning can be deferred the better. Celery should be finally earthed up, and some protecting material provided for covering it in the event of severe frosts. Potatoes, whether for seed or immediate use, should be kept as cool as possible, but, at the same time, effectually secured from frost. Flower borders should now be thoroughly cleared from all decaying vegetation and lightly forked over, as the bulbs will soon be coming through, and, if disturbed, after growth has commenced, they are easily injured.—J. G.

THE ARBORETUM.

PLANE TREES IN LEICESTER SQUARE.

PLANE trees are being planted in Leicester Square. This is a good omen; for trees that made many a nook and corner of old London pleasant places, have been fast disappearing, and with but few attempts to replace them. Whether the remarks made by the horticultural press in noticing the improved state of the square, were the means which led to a colony of Plane trees being planted in the space, or whether the idea may have arisen from sources entirely independent of those suggestions, is immaterial—the fact is sufficient. These Planes, if they have been properly planted, will, no doubt, thrive well, and serve to prove that at all events Planes will do well, even in the very heart of London, if there be anything like sufficient light and space, as in Leicester Square. The new opening from Oxford Street to the north side of this open space having been decided on by the Board of Works will impart to it much increased importance; and, in approaching it through the densely built portions of Soho, the group of trees in the now handsome arena will form a light and pleasant vista terminating the dark avenue of approach between long lines of houses of dingy brick; and, by increasing the value of the property, will eventually lead to the erection of a brighter and better class of buildings along that line. The proposed new approach to Leicester and Trafalgar Squares direct from Oxford Street will be very easily effected by the demolition of a few houses on the north side of Leicester Square, and a few more in the rear, which will at once open up a direct communication with an already existing line. The carrying out of this plan is so obviously simple that the only wonder is it was not effected long ago. When completed, the excellence of the alteration will be so apparent, that it will doubtless lead to further innovations almost as loudly called for—namely, an entirely new laying out of the irregular network of old and narrow streets, which form a very objectionable feature in that part of the metropolis, so close upon the handsome regions of Waterloo Place, Pall Mall, King William Street, and the destined opening direct to the Embankment, over the site of the demolished Northumberland House. These alterations will serve to connect our great leading West-end thoroughfares together, an improvement much to be desired.

H. N. H.

ACTINIDIA VOLUBILIS AND KOLOMIKTA.

THE *Actinidia volubilis*, which, many years ago, under the generic title of *Trochostigma*, was considered synonymous with the *Actinidia Kolomikta*, should certainly be re-classed with the species of *Actinidia* to which it properly belongs as is shown by its presenting all the leading characteristics of that genus. The accompanying illustrations show that some differences exist between the *Actinidia volubilis* and the *Actinidia Kolomikta*; they are, however, both natives of Japan, and are, especially the *volubilis*, well worthy of cultivation as climbers for covering bowers and arbours, trained Vine fashion. They have, however, one drawback which we must notice—they flower so very early in spring that their buds are often destroyed by frost, which not only checks their growth but prevents their blooming again during that season. They will grow in almost any soil, but they succeed best in a cool light one. They may be raised from slips and cuttings, which nearly always strike root well. The *Actinidias* are climbing Ternstroemiaceous shrubs, natives of the Himalaya, China, and

Japan. They have entire leaves and axillary flowers, and make useful wall plants.

C. H.

The Annual Lopping of Ornamental Trees.—The *Bulletin du Cercle Professoral* of November, 1872, has the following interesting notes, by M. Fr.

Bernevich, Professor of Arboriculture in Ghent, on the advantages of annually lopping certain ornamental trees:—"In an article entitled 'The Culture of *Paulownia Imperialis*' we have made known to our readers a very simple method of obtaining from this tree annual shoots, which, in size and beauty, will vie with the most handsome herbaceous plants possessing coloured foliage. We then expressed an opinion upon the probable success of annually lopping certain other trees. We are now able to state that the *Ailantus glandulosa*, when planted in good soil and annually lopped, produces one or several shoots, which will attain the height of 7 feet, throwing out to a distance magnificent feathered leaves, which resemble gigantic Fern fronds. A splendid

annual vegetation is also obtained by applying this culture to *Catalpa syriaca* (*Bignonia Catalpa*), *C. Bungei*, and *C. Wallichii*. The handsome variety introduced by our excellent colleague M. N. Gaujard, nurseryman at Ghent, becomes, by lopping, one of the most beautiful of ornamental trees for lawns. The *Rhus elegans*, *R. juglandifolia*, and *R. typhina*, are also plants to which this yearly

Actinidia volubilis.

Actinidia Kolomikta.

system of pruning may be applied with good results. The *Rhus glabra laciniata*, a still more recent acquisition for the plantations of landscape gardens, is one of the most graceful of plants when producing annual shoots. We must not forget, also, to mention the elegant *Aralia japonica*, *spinosa*, and *Maximowiczii*, nor the beautiful *Dimorphanthus Mandschuricus*, which should be more widely known. The public will, without doubt, soon be convinced that a grand secret lies in this system of annual lopping. Trees treated thus will yield leaves quite as handsome as those afforded by the *Wigandia*, *Udea*, *Ferdinanda*, *Heracleum*, and others, in the gardens of Paris and London."

Fertilising Aucubas.—Your correspondent, "W. N." (p. 525), may easily induce his Aucubas to bear berries without placing the plants in frames and without the expense of purchasing pollen or even the use of a camel-hair pencil. All he has to do is to graft a spray or two of the male plant on any female which he has. A few years ago I grafted on some female bushes, some of them from 10 to 20 feet in diameter, a spray or two of the male Aucuba, and they have been yearly covered with berries ever since. One graft will do for a bush a yard in diameter. Planting or placing males by the side of the females I have not found to answer so well as grafting. The grafts should be inserted at the top of the bushes. The green variety sets larger clusters of berries than the spotted one; when I graft, which is in May, I remove the tips of the shoots of the male plants, take similar tips off the females, and graft the male tips upon the female plants; a little firm clay is then squeezed round the ligature. In the autumn an examination is made, and, if a union has been effected, the ligature is taken off. The following spring, grafts put on in this way will flower, and the work is accomplished not for one season only, but for many without farther trouble.—H. M. E.

Raising Black Walnut, Butternut, and other Trees.—Will you give me directions for preparing and planting nuts of the Chestnut, Black Walnut, and Butternut? Should they be kept fresh till spring by putting in moist sand, and stored in a cellar, or planted in rows in autumn, and allowed to freeze during winter? Also the proper time to gather seeds of the Sugar Maple and White Elm, and how and when to plant?—L. O. [The nuts of the Black Walnut and Butternut should be gathered in autumn, when ripe, and placed in heaps on the ground, covered with inverted sods and some earth, so as to prevent too frequent freezing and thawing. They should be planted in spring, in good soil, about 2 inches deep. Chestnuts must not be allowed to become much dried; but, as soon as gathered, mixed with moist sand, and thus kept damp (not wet) all winter, in a cool place, and planted about an inch and a half deep in spring. Before mixing with sand, they should not be placed in large heaps together, or they may ferment and spoil. The common failure to grow is because the horny shell or covering and the kernel are permitted to become hard and dry. The Elms ripen their seed early in the season, and, as soon as gathered, they should be planted, not more than 1 inch deep; and, if the soil and weather are moist, half an inch will do better. The Sugar Maple ripens seed in autumn, when it may be sown, or mixed with damp sand and kept till spring in a cool place, taking care it does not become wet and rot.]—*The Cultivator*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Ivy and Dry Houses.—At one of the meetings of the British Association at Belfast, Mr. Frank P. Fellows confused us with the idea that plants like Ivy growing on the side of a house tended to make the walls damp. He knows a row of houses, the only dry one among which is covered with Ivy.

The Honey Locust as a Hedge Plant.—In a discussion among leading horticulturists at the city of Rochester, the Honey Locust (*Gleditsia*) was pronounced the best of all deciduous hedge plants. This opinion was shared in by Messrs. Elwanger, Barry, and other of the most extensive planters of that region.

Trees for Hedgerows: H. S. Any of the following trees will suit for hedgerows:—*Ulmus campestris*, *glabra*, *suberosa*, and *montana*, with their varieties; Oak, Ash, Sycamore, and the Black Italian Poplar, when planted 50 yards apart, are also suitable. The stems should be close and gradually pruned of side-branches until 15 or 20 feet in height. We should advise the growth of the better kinds of hardy fruits in such positions.

The Golden Chestnut (*Castanea chrysophylla*).—A lovely small tree from California; leaves, bright golden yellow underneath. At Heatherside it has proved quite hardy, having stood out unprotected for three winters without injury. Last year's leading shoot measured nearly 3 feet. It is so distinct and so beautiful that it ought to have a trial in every collection.—*Heatherside Manual*.

Root Fungi.—On taking up a young specimen of *Pinus Lusembiana* a few weeks ago, which I had planted out in the reserve garden to make a summer's growth, and have now removed under glass, I found that nearly every root and rootlet was covered with a snowy white sort of mildew. What is the cause of this disease, and what had I better do with the roots? I had noticed that the plants had made very little growth during the past year, but could not imagine what the cause was.—H. B. [The roots have, doubtless, become attacked by Fungi, owing to their having been placed in contact with dead stumps or roots of some kind. You might try the effect of shaking the soil away from them, washing the Fungus off with tepid water, and re-potting; but the better way would be to throw the plant away and get another.]

ARCHITECTURE AND LANDSCAPE.*

BACON commences his essay on building with the curt axiom, "Houses are built to live in, not to look on." The observation, the truth of which, from one point of view at least, we ought to be ready to admit (for is not the useful the foundation of the true in architecture?) savours of the practical wisdom of a philosopher not to be taken in by shows or pretences, and yet the learned Chancellor forgot one-half the truth. He forgot that houses or buildings of whatsoever class have to be "looked on," whether built for that object or not. Pictures and statues are made emphatically to be looked at, though unhappily they are not always worth looking at; but there is this to be said in their case, that if you are displeased with them you can always put them out of sight somewhere or give them away to a friend, or, if a man is unfortunate enough to admire a bad painting, at any rate he does it in private, and his taste is not necessarily imposed on his neighbour or on the public at large. But the case is otherwise in regard to a building. Be it good or bad, there it is; you can neither get rid of it nor hide it. It may be a blot upon the landscape, an annoyance to every one with senses open to such annoyances, but so long as its owner is satisfied there is no appeal; indeed, even if it be otherwise, and if the owner or his architect be stricken with repentance for his deeds, the toy is too expensive a one to be removed and replaced. It, therefore, behoves those who are going to place such an object permanently on the face of the country to consider well what they are doing, and to contrive their production so that it may not be a stumbling stone and an offence to the traveller in search of the picturesque. But this very relation of the building to its surroundings, this self-assertion of the edifice as a portion of the scene in which it stands, if it makes one of the difficulties, ought also to be one of the glories of the architect, for this is a kind of compensation to him for the restriction of his art in some other respects. It is useless—at least it seems so to me—to claim for architecture anything like that intensity of interest which belongs to works of art dealing with human feeling and human expression. The most picturesque combination of wall and roof and turret, pleasing though it be, in itself speaks to us in but an uncertain language compared with that which addresses us from the canvas of a Leighton or a Gérôme, from the marble fashioned after the thought of a Foley, a Woolner, or a Carpeaux. Nor does the production of a picturesque building require anything like that genius and concentrated study by which alone, and then only with the devotion of a lifetime, the complete power over expression by means of the figure can be mastered. But the architect is the generaliser among artists. The charm of his work is not in itself alone; it is in the understood or expressed relation which it bears to human life on one side, and to external Nature on the other. The mansion or the cottage is not the mere stateliness of marble and mosaic, the mere picturesque of timber and tiling. It represents—or should represent—the decoration of the daily wants of life on the one hand, and the relation of that to the grander decoration or scenery of Nature on the other. Inside his building he need not disdain attention to the minutest comforts or graces of life; outside it he need not restrict his interest within any narrower limits than are bounded by the visible horizon. From wherever his building is seen it becomes a part of the scene, often the central point of interest in it; it breaks the declivity of the hill side, or it aids the perspective of the level plain; it rises from the bosom of dark masses of wood, or it looks out like a sentinel from a bleak sea coast; but in each of such situations, or in whatever other site it may be placed, it will be interesting and suggestive in proportion as its architect has appreciated the predominant character of the scenery, and has known how to render his building in harmony with the genius of the place, and with the perspective and contour of the predominant features of the landscape. At the same time it is no easy matter to theorise, even, upon a subject which from some points of view appears so vague, and which certainly is scarcely reducible to fixed rules. But hints and suggestions may be gained in looking at what has been done, and comparing the effects of different combinations. Now in regard to the relation of that most conventional and most refined type of architecture—that of the Greeks—to landscape, there is much to interest us, and a good deal has been said on the subject, and that, it must be confessed, in somewhat contradictory tones. The late Professor Cockerell was of opinion that the Greek temples were specially adapted for effect in somewhat rocky and desolate sites, or that the Greeks specially accommodated them to such sites by giving heavier proportions than in plains; the one statement seems rather contradictory of the other. A contemporary French critic confirms this view, and thinks the temples were designed with special reference to their sites. A distinguished philosopher, Mr. Herbert Spencer, has on the other hand expressed the opinion, in an essay which shows how loosely philosophers can write when

* Read before the Architectural Association, by Mr. H. H. Statham, Jun.

they get on unfamiliar ground, that regular architecture cannot by any possibility be suited to an irregular site, and that any picture representing such a combination is essentially unpicturesque. Where shall we find the concord of this discord. I think the philosopher must go to the wall.

Greek Temples and their Surroundings.

The remarks of Professor Cockerell on the temples of Ægina and Bassæ are sufficiently to the point to be quoted. He says that "the Greek temples were seldom situated out of or away from cities except on special occasions, as when they were built on the site of some supposed remarkable event. When temples were thus situated, their remoteness, as well as the grandeur of the scene and the wildness of the country by which they were approached, formed a powerful contrast with the highly-finished object towards which the footsteps of the devotee were directed. . . . Surrounded by such scenery, we at once admit the fitness of these sturdily and stern proportions, both of the parts and of the whole, so much in accordance with the nature of the site, but so lamentably ineffective in a less conspicuous situation, or when placed in the midst of a crowded metropolis, and on a level with the public streets." I understand this passage as referring only to these temples of unusually heavy proportions. The author continues:—"So sensible were the Greeks of this fact, that we find different proportions generally adopted when the temple was placed on a plain or in a city. Generally, too, we may be permitted to remark that architects have adopted a low and horizontal system of architecture to a lofty country, and a perpendicular and aspiring one to a level and flat district, as if conscious of the inefficiency of all attempts at loftiness amid the wonders of mountain scenery, and seeking rather by the regularity of Art and succession of horizontal lines to present a contrast to these rugged irregularities of Nature." Your excellent secretary, Mr. Clarkson, was kind enough to point out this passage to me when I first mentioned the subject to him. Cockerell's remarks point to Greek architecture as a style of contrast to, not of sympathy with, the landscape—contrast at least in regard to the lines of the composition. In regard to the relation to the sentiment of the landscape, his remarks are not quite consistent, as he in one passage attributes effect to the contrast of the finished object of Art with the surrounding rugged scenery, and in another to the harmony of the stern proportions of the building with this same character of scenery. I believe the latter is the correct view. Contrast of the composing lines, and harmony of the general proportions and character of the building and the scenery, are conditions not only perfectly compatible with each other, but which, I believe, we shall generally find existing in the most fortunate instances of architectural and scenic combination. We see the same kind of effect in the restoration of the temple at Agrigentum by M. Viollet-le-Duc, engraved in the October number of the *Gazette des Beaux Arts*; and I do not think this building would be nearly as effective as part of a picture if it were placed on a level lawn; at the same time, the harmony of sentiment is preserved here, for there is nothing wild or stern in the site, only a degree of picturesque irregularity, softened, to a certain extent, by the forms of the foliage. It is of some interest to note how painters look at the subject, and in what combination they find their best or most favourite effects. If we take one of the great painters who has made most use of architecture in his landscapes—Claude—we find him in a great measure carrying on the subject for us. Sketching chiefly in Italy, Claude used in his classic architecture almost exclusively (indeed, I think quite exclusively, so far as columnar architecture is concerned) the taller and slither proportions of the late Greek and Roman orders. His "*Liber Veritatis*" gives a number of instances of the combination of this school of architecture with landscape, often of a more or less picturesque character, but not stern or rugged, and in many instances of a quiet and restful character, where his favourite architecture is combined with sloping banks and foliage. Now this late classic of Claude's goes remarkably well with the trees and the rounded contours of the land, but the early Doric I think we feel instinctively would not do so unless in a ruined state; and a building in that condition loses its original character a good deal, and becomes, in fact, more or less a part of Nature. There is one curious instance in which Claude gives us castles and towers at the foot of a rocky hill and a circular temple on the top; this seems to be out of place rather; but there is this to be said, that though in a northern climate we connect the idea of inclemency and exposure with a hill top, the absence of this association in a milder climate may give a different effect. We find, then, in the greatest painter of classical landscape (unless we except Gaspar Poussin) the classic columnar architecture associated in the main with landscape either of a quiet rural nature, or with picturesque but not wild or rugged scenes. If we wish to compare with this the impressions of a painter who has shown a special predilection of com-

binations of Gothic architecture with landscape, we need not go far for instances from a far mightier hand than that of Claude. If the latter is the artist of classic landscape, Turner is still more uncontrovertibly the artist of romantic landscape, and with that of romantic or "Gothic" architecture. No painter has more largely employed architecture as an integral part of his painted poems—none has more intensely felt its relation to landscape, its value as assisting and intensifying the feeling of a scene, and as giving point to a composition both in regard to outline and to the opposition of light and shadow. Over and over again we find in the works of this king of landscape painters, that it is a building which gives the key to the expression of the scene—weather it be a tower rising black and threatening against the light—a minster or cathedral crossing with its vertical lines the level evening sky, or standing as the centre of the radiations of the rising sun, which seems to form an appropriate glory around it—a castle which seems to stand the one unshakeable object amid the driving tumult of a gale on some bleak coast—a spire which sends up a pyramid of light into the sky—or perhaps some one small building, insignificant under some aspects, but which has been seized by the painter at the moment when a ray of sunlight has found it out, and forms on the canvas the one spot of high light to which all the rest is subordinate, and in default of which the power and meaning of the work would vanish at once. It surely adds one more motive for our interest in architectural work, both in regard to itself and its relation to Nature, to notice how its monuments have been incorporated by scores, by the hand of the greatest delineator of landscape the world has ever seen, in works whose poetic power will be felt and admitted as long as canvas and colours can keep them in being. It is worth while to notice, also, the distinction between the objects aimed at by these two typical landscape painters of the classic and romantic school respectively. Claude, in his sketches and studies especially (and it is in this form that the bent of an artist's nature is most truly discernible), is evidently aiming chiefly at a graceful and picturesque contour and outline composition, and an idyllic grace almost peculiar to himself. Turner is epic rather than idyllic, and it is at broad and massed effects of light and shadow that he mainly aims—many of his "*Liber Studiurn*" sketches being, in fact, little more than studies of effect, in which outline is secondary or nearly lost. In the landscapes in which his buildings form such important features, the attention is more directed to the wide sweep of distances, or to the expanse of sunlight and cloud shadows over foreground and middle distance, than to those picturesque irregularities of rock and foliage composition in which Claude found such characteristic pleasure. And the favourite architecture of the two painters evinces the same kind of contrast, the same leaning towards elegance in the one, and towards mass and grandeur in the other; and it would not be possible to point to a more striking instance of the distinction between the classic and the romantic feeling in landscape architecture than we find on turning from any of Claude's elegant compositions, with their colonnades fringed by light foliage, to such a threatening mass as that of Turner's Kidwelly Castle—a kind of thing that no one would have thought of painting before the present century.

Gothic Architecture in Connection with Landscape.

We shall find hints in further consideration of this subject from some of these specimens of Turner's treatment of architecture and landscape; but the important part which Gothic buildings play in his landscapes may lead to the reflection, how far the builders of our mediæval cathedrals and churches had any view to their effect in regard to the landscape. Generally speaking, I am strongly inclined to think that the feeling for landscape is a very modern one, and I am somewhat sceptical about the perception of picturesque beauty with which the Greeks are credited. The Gothic architects, however, seem certainly to have had an instinctive feeling in regard to the effect of site upon a design, especially noticeable if we contrast the design and position, for instance, of Lincoln Cathedral with that of the tall thin spires that rise up from the flat country round it. There are no landscape painters, no Turners and Claudes of the period, to show how the buildings appeared to them as matter for picturesque illustration; but I noticed the other day, in turning over some of the illuminated MSS. at the Lambeth Palace Library, some sort of indirect evidence on this point in the filling in of the background to the initial letters in one or two works. Leaving, however, the consideration of what painters of the past have made out of architecture in connection with landscape, can we, from the hints given us by these, and from other sources, arrive at anything profitable or suggestive towards providing material for painters of the future by so combining our buildings with the scenes in which they are placed that each shall heighten the effect of the other, and that the building, instead of appearing an intruder on the landscape, shall rather appear to be its natural complement—the last grace

added to the scene? If it be said that the subject is vague, that you cannot lay down rules in regard to it, that success in combination must be the result of innumerable small circumstances and of generally cultivated perception of sentiment rather than of rules, let all this be true (as I think it is), still that is not a reason for avoiding all consideration of the subject, but rather for urging attention to it. Does it receive sufficient attention at present? There is a story of a man being brought up in a New York police court for illegally painting an advertisement on the pavement, and that the charge against him was worded "for defacing natural scenery." Would not the magistrates in some districts have their hands pretty full if all the authors of buildings against which such a charge could be levelled were brought up before them? We may congratulate ourselves on having improved in the main the state of things since Repton had occasion to say in his work on "Landscape Gardening":—"I have often seen the absurdity of designs being made for a house where the builder had never seen the situation." Scarcely any architect would do this now; but I think it is true as far as this, that not unfrequently preliminary sketches are made before the site has been seen, and then the upshot of the matter is that the original idea, made independently of the site, is fitted to the site as well as may be, rather than disturb an idea at once formed.

Four Kinds of Sites.

Looking at the question a little more generally in regard to the nature of the problems to be dealt with, we may perhaps consider landscape, from an architect's point of view, as presenting four different classes of site—hilly country, flat country, wooded sites, and those in contiguity to water, whether on the coast or inland. We noticed the almost universally admitted theory and practice which suggests that the hills should be occupied by somewhat low and solid-looking buildings, and the plains by loftier and less bulky ones. This is not only, however, for the reason mentioned by Cockerell in the quotation relative to the Greek temples, viz., that architects were afraid of seeming to compete with the mountains, but also because the exposed nature of a site on the summit or brow of a hill inevitably suggests the necessity for strength and solidity of construction; the castle-like building of square proportions and massive walls boldly mounts the hill, the more delicate building with its fragile spirelets and lighter construction keeps under safe shelter at the base. But this treatment of hill architecture is subject to modifications. Mere elevation is not alone in question, but the character of the eminence—for what will look well on a bare and precipitous or rocky eminence may look very unsuitable on one of gentler and more rounded character. Looking at Turner's view of Powis Castle, for instance, I should say that a modern architect would make a great mistake were he to place a building of such massive and castellated character in that position in such a scene. As it stands, it has the prestige and association of antiquity to hallow it, but, as a new mansion, it would be a mistake. That regularly sloped hill, with the platform on the top, affords a suitable basis for a structure of less stern and more palatial character. So also Kilgarron Castle is picturesque enough as a view with an old castle in it, but the wooded slopes indicated in the original, at least, would scarcely bear so rude an intruder if in a modern dress. In general, rounded undulating hills require the more modest and ornate treatment of the architecture; square and abrupt ones, approaching to the nature of precipices, demand a correspondingly stern character in any buildings that are to look bold enough to have a right to claim footing on them. And something depends on the manner in which the building is accommodated to the ground. On a comparison of examples I think it will be recognised that the quieter and more reposing effect is gained when the building appears to be placed flat on the surface of the ground, even when on a considerable elevation; the sterner and more monumental effect when it is so treated that its basement is at an irregular level, at one point reaching down into a declivity of the site, at another seeming to climb into a ledge or projection. We see the former effect in Turner's view of Blenheim, which stands fair upon its plateau as a level and extended base, with a look of entire repose; this view struck me as interesting, also, as it shows Turner for once indulging in a style not unlike Claude, in the effect of the classic foreground architecture and wooded landscape. In Claude's own compositions it is probably to be attributed to this level base line that his little circular temples, though placed sometimes on rocks and precipices to match, do not look out of keeping; they have no appearance of really belonging to the situation—they rather look as if they were put down there for ornament, and might be taken up again. Instances of the contrary effect are seen in the remarkable view of Lillebonne, from Turner. Here the castle seems to rise in the midst like an outgrowth of the rock on which it stands, and into which the outer angles of its towers reach down, while, at the

inner angles, the rock seems to climb up to the towers. A small sketch from Mr. Ernest George's book of "Sketches on the Moselle" shows the same kind of effect. Treated thus, a building conveys the impression of being an integral part of the site on which it stands, and, when it can be used, there is no more certain source of architectural power and durability of expression. I have noticed this even in such comparatively common-place things as the tall old Edinburgh houses in the High Street and elsewhere, of which even the street front looks high enough, but when you come to the back you find the masonry descending sometimes as many storeys below the street level to find a firm footing on the steep slope. The effect is quite surprising to eyes accustomed to the flat basement lines of many other towns. Buildings placed on the site or slope of a hill are susceptible of rather different treatment from those on a summit. There is not so much room for boldness, for the building is, as Dugald Dalgetty would have said, "slighted or over-crowded" by the hill, and in general a square low form seems the most suitable for hillside architecture. This is especially the case when the hill forms a tolerably regular slope, in which case the form of a rather horizontal building makes a kind of break or parenthesis in the slope when viewed in profile. Irregular groups of buildings on a hillside are nearly always pleasing, and are a favourite incident with Turner. But single buildings in such a situation are generally best kept long and low in outline; and while a building on the summit of a hill seems to demand some sort of cupola or finish, by way of crowning the edifice, on the side of a hill this is lost, and is not needed, as the building never suggests itself as a final point in the composition, but only as an incident *en passant*. An instance of a remarkably picturesque terminal building on a high summit, varied in sky-line and yet sufficiently solid and massive for the position, is given in a sketch from a photograph of a palace at Cintra. Buildings on a flat and undivided plain present little for remark, as the architecture in such a case has it all its own way, so to speak, and the only thing to be observed in relation to the nature of the site is to take care that the building has sufficiently elevated features to compensate for the low level of the site and the want of a position of vantage to see it from, and to enable it to be seen at a considerable distance. This is in regard to a wide plain out of the neighbourhood of mountains; but in a low site surrounded by hills the case is very different. A certain elevation is still necessary, but it is useless for the architect to think of competing with the mountains, though I know one or two cases where this has manifestly been attempted (in regard, I mean, to massiveness of scale and general proportionate size), and his best chance of a pleasing effect in such a site is to accept the humble position in which he finds himself in regard to Nature, and to give to his building that appearance of simplicity and repose which will cause its position of retirement under the shadow of the protecting hill to appear perfectly natural and suitable. In the case, again, of a country neither absolutely flat nor bordered by hills, but varied by tolerably uniform and quiet undulations, a long horizontal treatment of building will be effective as affording a kind of definite line for the eye to rest upon amid the wavy and uncertain contour of the landscape.

Architecture and Trees.

The combination of architecture with a wooded country seems a more complicated matter for consideration than the two previous conditions; partly, perhaps, because we are accustomed to associate with trees such a multitudinous idea, both in regard to the number of species and the endlessly varying lines and breaks of contour which they produce. Yet by one of the most respectable authorities on such subjects the matter is condensed into a very few words. Repton, in his work on landscape gardening, says that, from a landscape gardener's point of view, there are only two styles of architecture, the "horizontal" and the "perpendicular," or "Grecian" and "Gothic;" unless, he adds, we may name a third under the head of the "fantastic," or, it may be called, the "Chinese." The worthy gentleman meant what we should now call "tea-garden" architecture, still preserved in many of our parks. His views about architecture, if we consider them in detail, are old-fashioned enough, but there is plenty of good sense and good taste in Repton, and many of his suggestions are very well worth considering in the present day. Proceeding with his simplification theory, he classes trees also in two main divisions, the round and the pointed. As to the relation between these and the two styles of architecture, he is of opinion that "trees of a pointed or conic shape have a beautiful effect with Grecian architecture; though an association with the ideas of Italian paintings, where we often see Grecian buildings blended with Firs and Cypresses, may also have some influence on the mind." There is no doubt that association of this kind does influence us very much in such matters; so much so that it is not easy always to discriminate between the result of association and that of unbiassed judgment. But I am inclined to think Repton's

decision is a perfectly reasonable one, and that trees of a vertical tendency, and of a tolerably symmetrical character of growth, do blend well with a horizontal building. At all events I think it quite clear that they do not go well with a vertical one; they confuse and weaken its effect. Repton's necessary conclusion, of course, is that Gothic buildings go with round forms of trees, because, he says, "they have a varied sky line, and hence are peculiarly suited to sites where the shape of the ground hides the lower part of the building, while its roofs are relieved by trees, whose forms contrast with those of the Gothic outline." We do not, in the present day (at least I hope very few of us), go about dropping a Grecian building on to the country here and a Gothic one there, just as fancy and the nature of the site may determine; but, in their essential meaning, these remarks, if true, are as true now as when they were written. Further on we find sentiments on the subject of combination of the house with landscape, which are quite refreshing: "When the lawns, the woods, and the water, and the general face of the surrounding country, are on so extensive a scale, the only means of preserving the same characteristics is by extending the plan of the house also; and how can this be effected unless we adopt the Gothic style of architecture? In Grecian or modern buildings it has been considered an essential part of the plan to conceal all the subordinate appendages of the mansion. Gothic enables us to use these in extending the design." Now, though Repton's notion of Gothic would probably horrify most of us, yet there is excellent sense and true perception of architectural treatment in this. Repton illustrates this by the view of Bayham, in which he points out how the size and extent of the buildings, which are formed round a large quadrangle, are clearly traceable through the contours of the foliage, and thus the idea of largeness and extent is conveyed which could never have been obtained had the house been combined into a single block, and the offices planted out of sight. Indeed, upon this system, formerly so universal, and still practised to a great extent, of planting the offices out of sight, Repton is sarcastic, saying that he has often been required to plant trees for this purpose, which, during the lifetime of the architect and the owner, never do conceal the offices, and which, in the lives of their successors, always have to be cut down to give a free circulation of air to the buildings. One other remark is worth quoting, viz., that "no form of building, as a rule, looks so insignificant in a landscape, in proportion to its actual size, as a cube," a fact which I have had occasion to verify myself in an instance I shall mention, and which is owing to that form presenting nothing to lead the eye in any one direction of length, breadth, or height. He adds very pithily that "symmetry may make an extensive building look small; irregularity will make a small building look large." In thus referring to Repton, Mr. Statham said:—I have purposely avoided alluding to anything connected with landscape gardening, which is the main subject of his work, because my object in this paper was to speak of architecture only in its connection with natural landscape in its widest sense. But I would advise those interested in the matter to look up Repton; allowing for the difference in architectural insight and knowledge in his day, they will find a great deal that is both sensible and suggestive. He was the acknowledged authority in his own day; and one of the most amusing chapters in Jane Austen's best story, "Mansfield Park," describes a dinner-table discussion as to the beautifying of a mansion and grounds, in which "Mr. Repton" is frequently referred to as constituting the court of final appeal. The principles he advocates, and which in the main I think are correct, would lead, however, to the conclusion that Greek architecture cannot well be assimilated with rounded and irregular foliage forms, which I should scarcely adopt: indeed, though I feel I am about to draw upon myself the contempt of the majority of my audience, I must confess that I never see the open colonnades in Hyde Park Gates, and the trees in the park through them, without being pleased with the effect; and here I think is again the condition of contrast of line, the symmetrical grace of the Greek "order," with the nonsymmetrical grace of the living foliage. As a combination of another kind may be noted the effect of the large heavy dark forms of the Yew trees in Hampton Court gardens, with the Palace as a background. The trees might have a better architectural background (with all deference to Mr. Stevenson), but the general effect is the same, and may stand as an illustration of the combination of conical trees with a heavy mass of horizontal architecture; the cone form is not acute or strongly marked, to be sure, but the character of the foliage is spiky, not rounded. The question as to the character of trees which ally themselves best with a building depends, however, very much on whether we consider it in regard to natural scenery, or to the formation of an artificial garden effect. In the latter case the trees are planted in some more or less symmetrical relation to the building, becoming really a portion of the architectural effect; and, perhaps, Hampton Court comes more under this category.

The Sea Side.

If we consider architecture in its relation to the sea and to sea-coast effect, there cannot be a shadow of a doubt to what form of expression in building the aim of the architect should be directed. The sea is always associated with ideas of power, grandeur, or of as desolating fury of the elements; and in many of the finest coast scenes the facts tally with the associations, for a considerable part of the year at least. The whole expression of a building to face the sea should be one of stern power and solidity. It should have the air of being rooted and buttressed in the rock, beyond all fear of being shaken or threatened by the invasion of the wind and waves. To my thinking the architect could hardly have a commission more calculated to stimulate his enthusiasm for the poetical side of his profession than the command to place upon a site overlooking the open ocean a building which should be in keeping with such a position. All the grander and more monumental effects of architecture, which modern life seldom gives occasion for, and even scorns at involving useless expenditure, are here not only permissible to him, but are actually the indispensable elements of success in his undertaking. He has a right by the very conditions of the problem, to be liberal in the thickness and massiveness of his masonry, to discard all prettiness and trivial ornamentation, to reduce the area of his window openings, to give to his walls that broad expanse of solid stone which shall seem as impervious to all buffettings of the wind as is the rock itself; he has to realise the fine line of the Poet Laureate, where he likens one of his heroes to a tower—

That stood four-square to all the winds that blow.

It is vexations to think that (partly owing, I suppose, to the nomadic or intermittent nature of seaside populations) seaside architecture in general is marked by so exactly the reverse of the characteristics I have endeavoured to describe—that seaside houses are commonly the type of all that is sham and rickety. No architectural object plays so important a part in landscape as a tower. In a flat country it is invaluable as an addition to the landscape; but it is also not ineffective in the neighbourhood of hills, provided they are not so near or on so large a scale as to dwarf it. Turner, in his Salisbury, gives great effect to the spire by taking a view which causes it just to break the line of the hill behind—evidently with intention; and in his remarkably effective view of Harfleur, the great spire, white in the light, is rather aided in effect than otherwise by the sloping lines of the hill to the right. These and other instances in Turner would suggest that under such conditions a tower and spire should be so placed that from the best point for a view of them they should appear to overtop the hills and break upon the sky. In speaking of towers, it may be noticed that Claude, in his architectural subjects, almost always places in some part of his picture a plain heavy round tower as a kind of foil or contrast to his columnar or renaissance architecture. Turner seeks for contrast in his tower subjects, but he seeks for it in light and shadow; and where he has two objects of this kind of about the same size and importance, he always puts one of them in light and the other in shadow. Since it became my fortune to live almost, I may say, under the towers of Westminster, I have been constantly struck with the beauty of this effect. These two towers at either end of Westminster Palace seem to have all kinds of expressions as different lights fall on them; and you may step out to find the Victoria Tower clad in purple and fine gold, resplendent and glowing, while the clock tower wears an almost threatening aspect; turn a moment after, and behold the scene is changed, and the clock tower is all glitter, and its prouder neighbour has relapsed into gloom. If, then, the aspiring architect has the rare good fortune of having to erect anything large enough to have two towers, keep them sufficiently apart to afford room for this varied play of heaven's light upon them, this constant poetry of architectural expression. I cannot quit this subject without remarking on the interest and charm of the various views of the Victoria Tower which you get coming down the Thames from Putney or Chelsea. It is worth while to go a little way up the river to watch the effect of this tower as you come down again, and the varied aspects and perspective positions which it assumes. Few things in architectural effect are more striking than the use made of towers in the mediæval French chateau, where the dwelling part of the chateau is placed on a high rock or plateau, and the tower seems to plant a foot on the ground below, as if as a sentinel. Any one who examined the French Commission drawings in the International Exhibition must have been struck with the prevalence of this arrangement, and its remarkable effect upon architectural expression on plan as well as on construction. Turner was evidently taken with it, as his view of Chateau d'Amboise indicates. The part which buildings play in giving scale to the distance in a landscape is very important, and if the architect has any regard for the effect of his building on the scenery, he should endeavour to give it an

outline and proportion which will harmonise with the scale of the landscape, and to place it so as to afford an opportunity for assisting perspective effect. An instance of the value of a building in regard to this latter point is seen in a study of Claude, where the small building on the distant plain, evidently, from its outline, a building of the same class and size as that near the foreground, contributes largely towards increasing the scale and effect of the distance. The question of colour and tone is important, too, in its effect in connection with landscape. In the course of the expedition of this society into Northamptonshire, when I was a somewhat indolent member of the party, we visited a place called West Deeping, where there was a quiet old brown stone church of not very remarkable interest. At all events, it did not tempt me into sketching, and I strolled round to look into the water rushing through the milldam, and in so doing opened out a view of a brand new parsonage behind the old church, all red, black, and yellow brick, tuck-pointed, and everything proper. I did not get over the shock for some time, and perhaps you will feel as unkindly towards the brick parsonage as I did when I say that it first suggested this paper. This part of the subject, however, is far too extensive to go into at the close of a paper, but I think a general means of avoiding harsh and crude effects is to aim at employing, as much as possible, the building materials of the district, because these are what form the basis of the tone of the landscape, and though any new building looks raw and crude at first in the landscape, it will, if built of a material indigenous to the district, very soon begin to assume a harmonising tone. Not, however, that I would by any means speak slightly of brick as a picturesque material, but I confess to an absolute hatred of the buff or yellow brick. It harmonises with nothing; it is gaudy when new, and insipid and useless when weather-worn. But a rich-toned, not too bright, red brick looks very well in combination, especially with a wooded country. I noticed an observation in Repton (if I may refer to him once more) that a large red house is not displeasing, though he seems to think a small one is. I was struck with this, having observed in the architectural room of the Academy the last two or three years a tendency towards large red houses, and one I remember very well, though I forget the architect, where the red tone was carried in an almost uniform tint over the roofs also by means of tiles; the site was well wooded, close up to the house, and the effect, as shown in the water-colour drawing, was exceedingly pleasing. As to small houses, most of us remember the "red house" at Northampton. There is something, also, to be said for white in a landscape where grace rather than richness is the prevailing character. You will, perhaps, think I am naming rather a trivial instance, but in walking up St. James's Park, on some recent autumn mornings, I have been much pleased by the effect of the long white front of Carlton Terrace glittering in the sunlight, and seen through a network of thinly-clad trees. It would be pleasanter to think it was marble, no doubt; but let "Compo." have a good word for once. This kind of combination of white building with a screen of trees was liked by Turner, who has given a fine instance of it in his imaginary scene, called "The Garden of Boccaccio," in the National Gallery. There is one other point on which I should wish to raise a question, and that is in regard to a very prevalent and increasing disposition on the part of some of the ablest members of our profession, who, again, are imitated by their juniors, towards what can only be described as more or less a "rustic style" for large country houses. Some of the compositions of this kind, seen from time to time in exhibitions and in the illustrations of the architectural journals, are so picturesque in themselves, and are in the best instances set forth by such capital and artistically effective drawing, that the judgment is disarmed on looking at them. Yet it is open to serious question whether this is, after all, the thing. In the first place it may be doubted whether the comparative refinement and culture of modern life, regarding which there is now little real distinction between the country and the town, meets with the best architectural expression in a building conveying the impression of being a group of cottages thrown together into a house, with a turret added as a leading feature; then, as to the connection of the house with the landscape; I used the word "picturesque" in regard to this style of house, and it is so, but it seems to aim at including all the picturesque within itself and presenting, one might almost say, the aspect of landscape and house in one.

Certificated Fruits and Vegetables.—The following received first-class certificates at Chiswick and South Kensington this year, viz.—*Beans*: Carter's Mammoth Long-pod, Carter and Co.; Seville Long-pod, Villmorin et Co.—*Potatoes*: Barron's Perfection and Early Dimmick, Farquhar; Boantifol, Fenn; Cattell's Eelipse, Cattell; Dwarf White, Bliss and Sons.—*Tomato*: Carter's Greengage, Carter and Co.—*Grapes*: Mrs. Pearson, Pearson; Venn's

Seedling, Sweeting.—*Musa*: Champa, Woodbridge.—*Pears*: Beurré de L'Assomption, R. H. S. Chiswick; Lucy Grieve, Grieve; Pitmaston Duchesse d'Angoulême, Kemp.

THE HOUSEHOLD.

Boiling Fruit in a Copper Kettle.—In preparing Apple butter in a copper kettle, where fresh cider is boiled down and thickened by adding sweet Apples cut in slices, and the whole kept on the fire for thirty-six to forty-eight hours, would the danger of poisoning be certain, and how would it show itself with the persons partaking of it?—JUB. A. [Answer by Prof. S. W. Johnson, in the *Tribune*: Acids like those in fruits as well as vinegar do not act on metallic copper, except with co-operation of the oxygen of the air. Therefore, Apple juice or vinegar may be boiled in clear copper kettles without danger of dissolving the metal, for the escaping steam excludes the air; but in the process of heating up and of cooling down in open vessels some copper will go into solution. If the process is quickly and skilfully conducted, so little copper will pass into the Apple butter as not to damage it or make its consumption unhealthy. But if the Apple juice slowly simmers for forty-eight hours, the quantity of copper dissolved might be highly injurious. Acute copper poisoning, following the ingestion of considerable quantities of soluble copper compounds, but not enough to produce speedy vomiting, occasions severe inflammation of the stomach, intestines, and liver, with vomiting, spitting, and bloody diarrhoea, also constant headache, yellow complexion, cramps, lameness, and staggering. Chronic copper poisoning is followed by the same symptoms, in milder forms, with weakness of the limbs, pallor, and waste of flesh. It is not improbable that weak, dyspeptic persons have these evils aggravated, and suffer severely from swallowing small amounts of copper that are totally harmless to strong and healthy people. The use of vessels of copper for cooking, of plated, lead-soldered tins, for canning acid fruits, of lead pipes for siphons, &c., in making vinegar, and for water service, occasions, in careless hands, an immense amount of suffering in the way of chronic poisoning.]

Apples.—With most of us the value of the Apple as an article of food is greatly underrated. Besides containing a large amount of sugar, mucilage, and other nutritive matter, Apples contain vegetable acids, aromatic qualities, &c., which act powerfully in the capacity of refrigerants, tonics, antiseptics, and, freely used at the season of mellow ripeness, prevent debility and indigestion, averting, without doubt, many of the "ills which flesh is heir to." The operatives of Cornwall consider ripe Apples nearly as nourishing as bread, and far more so than Potatoes. In the year 1801—which was a year of much scarcity—Apples, instead of being converted into cider, were sold to the poor; and the labourers asserted that they could "stand their work" on baked Apples without meat, whereas Potato diet required the addition of meat or other substantial nutriment. The French and Germans use Apples extensively. The labourers depend upon them as an article of food, and frequently make a dinner of sliced Apples and bread. There is no food cooked in so many different ways in our country as Apples, nor is there any fruit the value of which, as an article of nutriment, is so great and yet so little appreciated.

Potatoes Soufflés.—Those delicious blistered Potatoes are rarely or never seen on English tables. The Potatoes, if small, are simply cut in halves; if large, cut into three or more slices; these are fried in the usual way, but are taken out before they are quite done, and set aside to get quite cold; when wanted they are fried a second time, but only until they are of a light golden colour, not brown.

Lemon Butter for Tarts is made by using 1 lb. of pulverised white sugar, the whites of six eggs and yolks of two, together with three Lemons, including grated rind and juice; cook twenty minutes over a slow fire, stirring it constantly. Thus treated, it is excellent.

Potatoes Sautees.—These are even more agreeable with meat than fried Potatoes. Cold boiled Potatoes are sliced up, and tossed up in a saucepan with butter, mixed with a little chopped Parsley, till they are lightly browned. Pure goose or other dripping is by many cooks preferred to butter for this purpose. The acmé of delicacy in the cooking of Potatoes is achieved in what is called

Puree of Potatoes.—This only differs from English mashed Potatoes in the employment of more milk and butter, and in the whole being carefully reduced to a perfectly smooth thick cream-like mixture. Where economy is a great object, and where rich dishes are not desired, the following is an admirable mode of mashing Potatoes. Boil them till thoroughly done, having added a handful of salt to the water, then dry them well, and with two forks placed back to back, beat the whole up till no lumps are left. If done rapidly, Potatoes thus cooked are extremely light and digestible.

THE LIBRARY.

THE COMPLETE MEASURER.*

This concise manual, consisting of 380 pages, is one likely to prove useful to gardeners and others having occasion to measure either timber, stone, or other building and fencing materials. It is arranged on the ready-reckoner principle, so that all trouble in working out a series of intricate rules is saved. Not only are the best methods of measurement shown, and in some instances illustrated by means of wood-cuts, but the erroneous systems pursued by dishonest dealers are fully exposed. Taken as a whole, the work must be considered to

be a valuable addition to every gardener's library. The following extracts and illustrations will serve to show what may be expected to be found in such parts of the work as are not tabular:

To take the dimensions of a round tree or any similar body, measure its length in feet by a rod, tape, or carpenter's rule, and then take its circumference in the middle with a piece of common whipcord, doubling the cord into four equal parts, and so apply it to the carpenter's rule, to learn the quarter girth in inches with any fractional quarter or quarters of an inch that there may be. Or the circumference of the tree may be taken with a narrow, non-elastic painted tape having spaces of four inches marked upon it, each space

being numbered in successive rotation as girting inches, and every such space subdivided into four equal parts by a partial mark on the tape, to answer as quarters of inches. A purchaser will prefer using the whipcord, unless at the commencement of the tape $\frac{3}{4}$ of an inch is given in the measurement as an equivalent to him for the accustomed advantage obtained by the doubling of the whipcord to apply to the carpenter's rule to find the quarter girth of the tree. The tape when passed round the tree shows its quarter girth forthwith. These directions for taking the dimensions of a tree or pillar is under the consideration of its size being the same throughout, as instanced by the diagram No. 1; or of the tree or column tapering regularly from one end to the other, after the manner of the diagram No. 2. But when the size of a tree is not regular its whole length, in consequence of sudden variations in its circumference, each part or length of it so varying in girth must be measured separately, in conformity with the subjoined diagram, No. 3, and then the contents of the different parts added together. Having obtained the length and the quarter girth as directed, we refer to the top of the table for such quarter girth, and beneath it, opposite to the length of the tree found in the outward columns of the page, is shown the solid contents of the tree, or portion of the tree as may be.

Length. Feet.	Quarter Girth. Inches.	Solidity. Feet.
14	17	35½
9	11	9½
11	8½	7
		52

If the improbability ever should arise that the length or the quarter girth of a tree should exceed the limits of this table, the same method of ascertaining the quantity of the tree may be resorted to here as was pursued in the last table. Any part of a timber tree not girting 24 inches (that is 6 inches its quarter girth), is not usually considered timber, and is excluded from the measurement, unless by agreement to the contrary. To exemplify the principle upon which this round

timber table is compiled, and to represent how to acquire the true quantity of any round body, be its size what it may, as also to clearly show the construction of the square-sided timber table which Hoppus erroneously adopts for round timber, the above diagram of the transverse section of a tree with its demonstrations is extracted from my set of published calculations entitled "Underwood and other Tables."

The above circular figure, showing the transverse section of the tree, and the square figure that is substituted and computed by Hoppus in lieu of it, by considering one-fourth of the circumference of the circle sufficient for the side of a square that shall contain an equal area to the circle, fully demonstrates the fallacy of the customary method of measurement. It is obvious that the area of such a square must be much less than that of the circle, although the four sides of the one are equal to the circumference of the other. It is known that the area of a circle whose circumference is 1, is .0795, &c., upon which calculation I have computed the quantities in my table; but in this example I adopt the usual practice of substituting .08, as this deviation causes a considerable abbreviation in the calculation of the area of circles, with very little difference arising in the result.

To elucidate the tradesman's loss by Hoppus's mode of measurement, we will suppose a mason buys a square-sided piece of marble, measuring in each of its thicknesses 21 inches, and in its length 20 feet, for the purpose of making it into a circular pillar. By reference to the square-sided timber table it is seen this square piece of marble contains 61 solid feet. After converting it into as large a circular pillar as possible, it will girth 66 inches, and to obtain the solidity of it, Hoppus takes 16½ inches (the quarter girth of 66 inches), and refers to the square-sided timber table, where the quantity is given at 37½ feet in the round pillar, making a loss of 23½ feet in the conversion of the marble from a square to a circular column. By applying to this round timber table, it appears that the true content of the circular pillar, measuring 66 inches in circumference by 20 feet long, is 48 solid feet, and for which the tradesman should charge his customer, instead of for only 37½ feet, the false amount obtained from Hoppus's table. As a palliation for the extraordinary sacrifice thus made by the sellers of round timber, the

* "The Complete Measurer." By Richard Horton. Second Edition. With important additions. London: Lockwood & Co.

purchasers observe that they are entitled to an allowance for waste arising in hewing the tree. That an allowance ought to be made is unquestionable, but it should be a just one between the two parties, and to this end I would submit that the proportion of $\frac{1}{4}$ th of the solidity of round timber trees be allowed for the waste, and I here demonstrate my reason for coming to such a conclusion. Referring to the transverse section of the tree, I have its circumference before hewing 66 inches, and its side after the hewing 8 03959 inches, and I will suppose the tree to be 30 feet long.

EXAMPLE.—Required the content of a tree that measures 66 inches round and 30 feet long.

Rural Affairs.—This is the expressive title of a very interesting and well-illustrated volume containing excellent articles on farming, gardening, fruit culture, &c. It is an annual publication, issued at Albany, U.S., by the proprietors of the well-edited and in every way trustworthy *Cultivator and Country Gentleman*, which holds a very high position in the estimation of agriculturists in the United States.

PERSONAL.

MR. GILBERT, of Burghley, has written the calendar of operations in "The Garden Almanac" for the current year.—Mr. Philip Masey is the architect and landscape-gardener of the projected winter garden and aquarium at Liverpool.—Mr. Messenger, of Loughborough, is to build the new range of glass in the Glasgow Botanic Garden.—The managers of the Belfast International flower show (says the *Gardener*) have prepared and awarded to Mr. Hunter a special medal with a suitable inscription, &c., for the heaviest bunch of Grapes on record.—Mr. Lees, who has for thirty years been gardener at Tynningham, left that situation at Martinmas last, and has taken a farm and market garden in East Lothian. He served at Tynningham under three successive Earls of Haddington, and has all along been one of our very foremost cultivators of plants and fruits. Mr. Brotherston, from Arzyle Lodge, Wimbledon, has succeeded to the charge of Tynningham Gardens.—Mr. Peter Barr proposes to found an anti-Pelargonium society. He refuses to subscribe to the Pelargonium society on the ground that nearly every garden is already an experimental ground for Pelargoniums.—Mr. Cannell will shortly transfer his business from Woolwich to Swanley, near the Swanley junction of the London, Chatham, and Dover railway.—We understand that Mr. Ford, late gardener to the Duke of Manchester at Kimbolton Castle, succeeds Mr. Woodford at the Duke of Edinburgh's new residence, Eastwell Park. Mr. Barr succeeds Mr. Ford at Kimbolton.—Mr. Henderson, who for several years has had the management of Sir Henry Peck's garden at Wimbledon House, is about to leave, and Mr. Ollerhead is named as his successor.

VIRGINIA AS A GARDEN LAND.

VIRGINIA is a pleasant place, with something to remind an English eye of scenes near home. Her air is soft, her climate pure. Her fields are green, her uplands bright, her rivulets fresh. She fronts the ocean, and her ports are gay with sea-going ships. The world is open to her enterprise. Great friths indent her shores, and tidal rivers flow into her valleys. She is everywhere a water-power. A hundred sparkling rills drop down her woodland heights. Her dells

are dark with pools and lakes, her ravines musical with steps, cascades, and falls. Through every valley winds a shining stream, blessing the soil through which it flows, and carrying toward, and it may be seaward, the accumulated forest growths. But she has beauties of her own, the like of which we English only see in dreams. A ridge of appenines cuts across the country, separating the fertile Shenandoah Valley on the east from the still more fertile and enchanting Winchester Valley on the west. These appenines are called Blue Mountains, from the purple tinge, which in the twilight after sunset deepens into blue, as dark as that of either Syrian sea or Grecian sky. Virginia's sun is very bright, and in his brightness he is constant, nearly all the year. Fogs are unknown, and mists are seldom seen. This wealth of sunlight in the sky sheds wealth of colour on the landscape. Skies as clear, and streams as fresh, are found in many places; but this range of mountain woods is nowhere to be matched, I fancy, on the living earth. Fine groups of hills start here and there beyond the chain of heights; one alp called White Top Mountain, lifting its head high above the Righi and Mons Pilatus; high above the line that Snowden would attain if she were piled on the highest peak of the Cheviot hill. These giant hills are clothed with Pine and Maple, Oak and Chestnut, almost to the crown. Their sides are all aglow—gold, orange, scarlet, crimson, russet—all the burning colours of the forest mingling in one common flame. The glory of the falling year is nowhere, I imagine, to be seen in such perfection as in these Virginian alps. Drop into this garden, and again you feel at home. This orchard is an English orchard, and these Apples, Peaches, Pears, and Plums are English fruit. Here is a Potato ridge; you pull the plant and find it is an English root. But here are other things, well known at home, though not yet grown at home. In Kent, these Grapes would be under glass. These Melons would not be seen in any English garden, except Covent Garden; and these Pippins and Lady Apples are often seen on English tables, but are grown, I fancy, on Virginian soil. Here we have Maize growing in one corner, Tobacco in a second, Peanuts and Sweet Potatoes in a third. These roots and fruits are homely things to us, yet homely in a far-off and poetic sort of way, as the Roses of Sharon and the Lilies of the Valley are familiar to our thoughts. We draw nigh to them and feel at home among them, yet we recognise a sense of difference and of separation that clothes them with a kind of charm.—H. D.

The New Horticultural Club.—In answer to numerous enquiries addressed to me privately, which indicate that others would like the same information given to them, will you kindly permit me, through your columns, to say that the only reason why more active steps have not been taken in bringing it more prominently before the general body of horticulturists, is that, so far, we have been completely baffled in our attempt to find suitable accommodation, and that we are desirous, before issuing any further statement, to be able to say that we can offer our friends the full benefit of membership. The very cordial manner in which the proposition has been welcomed by representative men in the various branches of horticulture, leads the committee to believe that when we have completed our arrangements, we shall be enabled to establish the club on a satisfactory and permanent basis.—THE SECRETARY.

OBITUARY.

It is with great regret we record the death of Mr. John Traherne Moggridge, which took place at Mentone on the 24th ultimo. Mr. Moggridge had been an invalid for a long time, and for thirteen years has passed the winter at Mentone. There, in spite of great illness and a state of weakness which almost precluded his walking a hundred yards without suffering, he managed to do much valuable work in various branches of natural history. Two excellent books—the work of his pen and pencil—for he was equally expert with both—bear testimony to his merits as an observant naturalist. Mr. Moggridge's work on "Harvesting Ants and Trap-door Spiders" is a signal exemplification, not only of the author's acuteness and accuracy of observation, but of the wide field yet unexplored in very interesting branches of natural history. We allude to them simply as evidences of good work done under the greatest difficulties. The writer was fortunate enough to meet him at Mentone last April, and to hear from his own lips much of the interesting history of those harvesting ants and trap-door spiders, the habits of which he had studied to such good effect, and to gather with him some of the flowers on the hills round favoured Mentone, the flora of which both he and his father knew so well. Personally, he was most amiable and gentle in manner, and we look back to an afternoon spent with him in collecting, in mossy turf and wet banks about Mentone, the nest of the spider (so well shown in his book) as one of the happiest ever spent in like pursuits. Mr. Moggridge was an accomplished draughtsman, and illustrated his own books. We believe all his scientific work was done since he was stricken down by severe illness.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

FORCING POTATOES.

THE Potato is undoubtedly one of the most welcome of early vegetables, and a dish of young Potatoes in March or April is appreciated nearly as much as a dish of Strawberries. Both of these we have always contrived to have in quantity every Easter for the last ten years; Strawberries, of course, earlier than that; but the Potatoes I do not think worth having before the middle or end of March, unless as a novelty. I have known great pains taken to secure a dish or two before that time by growing the Potatoes in pots in hothouses, but the produce I never considered worth the time spent on it, apart from the question of space and materials. The Potato is very easily forced into growth, but unless the culture is conducted with some attention, very little crop, if any, is likely to result. Hence it is rarely forced, even in large establishments, being considered not worth the trouble on a large scale. This is a mistake, however. Apart from the gratification of having them on the table, they may be forced early in sufficient quantity to pay for the outlay in any private establishment. To do more than this, the frames must be utilised in another manner after the Potatoes are over, as I shall hereafter point out. It is perfectly hopeless attempting to force the Potato early unless the foliage can be exposed to the greatest amount of light possible, and the necessary temperature be maintained. I am not, therefore, going to recommend any haphazard plan, but one that will succeed if carried out properly. I must first say a few words about the Potato pit, which should be a brick structure, 7 feet wide and 5 feet deep at the back, and of any length required. This depth will allow of 3 feet of pit for a hot-bed of leaves, which will be necessary for the earliest crops, and half the brickwork may, of course, be below the ground level. A 3-inch hot-water pipe, taken along the back of the pit and round the front, will be ample heating power. The brick walls should be 9 inches thick, but the back wall may be "set off," within 15 inches of the top, to half a brick, which will be sufficient for the framework to rest upon; and the ledge so formed inside will be highly useful for Strawberries in pots, or bedding stuff, &c. Such pits can be built cheaply, and the sashes and excellent substantial framing can now be bought, painted and glazed with 21-oz. glass in readiness for fixing, for a little over 20s. a yard. I am describing the pits in use here for Potato forcing. They have paid themselves over and over again. After the Potatoes are over in April and May, a quantity of Tomato plants, which have been sown in February and pushed on to big plants anywhere about the Vineries, are planted in the frames and trained over the bed, a few old Pea sticks being laid under them to keep the fruit off the ground. From June till November we get enormous crops from these plants, with little or no attention. There is always a ready market for Tomatoes, and, what we do not use, fetch readily from 4d. to 6d. per pound in the nearest market, and it does not take many Tomatoes to weigh a pound. I record this fact for the benefit of those to whom the Potato frame is a question of expense. If the frames are not needed otherwise during summer, sufficient Tomatoes may be grown in them to defray all expenses. Presuming the first crop has to be ready towards the end of March, it should be planted about the end of December, and, with this object, 3 feet of leaves should be put into the pit a week or two before, and allowed to settle, after having been trodden hard when put in. It is not desirable that the bottom-heat should be above 65° or 70°; if higher than this it forces the Potatoes unduly during the dull winter months, and no tubers are formed worth speaking of. For this reason I never use a hotbed at all for the second crop—planted in February to be ready by May—and it is always the best. At that season, if the top-heat is properly maintained, sufficient heat will be imparted to the soil to promote a healthy growth; 9 inches of soil—light, loamy, spent soil, from an old Melon or Cucumber

bed will do well—should be laid on the leaves when they have settled sufficiently, or it may at once be thrown into little ridges with the hand, 7 inches deep and 18 inches apart, the ridges to run across the bed, supposing the pit to face south. The object of the ridges is to save earthing up the Potatoes, or top dressing, when they have grown, which cannot be done without abusing the tender stems. The sets are planted in the furrows so formed and barely covered at first, and after the stems have grown about a foot the ridges are levelled in about them, which can be done easily and expeditiously with the hand. The Potato, when forced, is very apt to form tubers near the surface of the soil, consequently moulding-up in some way must be done to prevent the best tubers from greening. Indeed, I have found it necessary, sometimes, to top-dress as well, where the stems were growing vigorously just when the tubers were forming. For this reason I have never forced any other kinds than *Mona's Pride* and the common *Ashleaf*; both are adapted for the purpose, as they make short tops—an important consideration in forcing. The *Royal Ashleaf* is too luxuriant a grower. I plant the first named for the earliest dishes, as it gets to a useful size soon; but the common *Ashleaf* is best for the main crop. Some advise saving seed from the earliest crops for forcing; but this is not of much consequence with crops planted in December. The Potato starts easily into leaf, after which the stem depends upon its own proper roots for sustenance, and the chief object then is to secure a quantity of good healthy foliage; weedy stems crowded thickly together will never yield decent-sized tubers. I select sound tubers, of fair size, a short time before the pit is got ready for planting, lay them closely together in a shallow box, and cover them with about $\frac{1}{2}$ inch of soil. They are started in any of the houses or pits where the temperature is about 60°, giving them scarcely any water at this stage. As soon as they have grown about an inch, or less, all the buds are rubbed clean off but one strong one, and the sets are finally planted in the bed, in the bottom of the little furrows before described, 6 inches apart, with the bud end of the sets all lying one way. They are then barely covered with soil, and planting is done; no water is given at this stage either. In this way I get twelve or thirteen sets into a row, in a pit of 6 or 7 feet wide, and I reckon confidently on each row giving, at least, one good dish of Potatoes, sufficient for a considerable party. If the single stem system is adhered to, each root should yield three or four good-sized Potatoes and some small ones. Avoid crowding the shoots. A good stout stem with a head of broad healthy leaves always indicates large tubers. I sometimes take the trouble to put a small stake to the stems, to keep them from falling down; when standing up erect to the light they receive its full benefit, and this is everything so early in the season. I have seen forced Potatoes with stems 2 or 3 feet long, lanky and soft, without a tuber above the size of a Bean at the root, and all through hard forcing and crowding. Little or no water should be given from the time they are planted till the Potatoes are fit to get in, unless it be near the pipes, where the soil is apt to get dry; the stems damp off readily if too much water is given, and, besides, the Potatoes are not good to eat. A night temperature of from 60° to 65° is quite high enough, and an abatement of 5° may be made in these figures in cold weather. On bright days it may run up to 75° or 80° with safety, but always with a free circulation of air. I do not adopt the usual practice of ventilating only at the back of the frame, as I find the plants placed there are much retarded, if not starved, by doing so, while those near the front pipes are roasted. I ventilate at the front by pulling the sashes up 2 or 3 inches, which allows the air to rush in over the front pipe, getting warmed by the contact before entering the pit, and, passing over the Potatoes, it escapes out between the glass and the wall-plate at the back. I ventilate all our frames in this way, as it ensures a more regular temperature throughout the structure, and cold draughts, such as result from opening the sashes widely at the back only, are completely avoided. When the crop is almost fit to get in, the pit should be kept dry, airy, and warm, though nothing like ripening the plants need be attempted. The object is to get good tubers fit for use as soon as possible; and, if they have been grown as here directed, rather on the dry side,

they will, when large enough, be ready for the table. For the second crop, to be fit to get in by the 1st of May, I plant in February; the treatment is the same, only that it is not necessary to use leaves for bottom-heat. By the above plan, Potatoes may be had when desired independently of the weather, but I ought to state that it is not necessary to go to the expense of building brick pits and heating apparatus to have Potatoes early. To attempt to have them as early as March or April, however, with the aid of fermenting materials alone, involves much labour and trouble, and the results are, at the best, uncertain. Still, with the simple leaf hotbed and wooden frames, they can be had a long while before the earliest outdoor crops are ready. Frames suitable for the purpose can now be bought cheaper, as a rule, than they can be made at home; they may be had, carriage paid to their destination (if within 200 miles), at exactly the same price (20s. per running yard) as the sashes for the pits before described, to which they are similar, so far as glazing, painting, and excellence of construction are concerned. Such structures are a capital investment for gardens of moderate extent, as they can be turned to almost any purpose, will last for many years with a little care, and, being portable, are, of course, the property of the tenant. For Potato forcing, such frames should be placed on a leaf-bed, and it is an excellent plan to thatch them with straw outside, which will save much trouble with linings in frosty weather. This thatching can be performed quickly by any labourer, for he has only to get a bundle of clean drawn Wheat straw, and tuck it round the outside of the frame with two or three lines of tar-band, hooking the band round a nail about every 2 feet, as he goes on, and afterwards cutting the straw square off with the knife, level with the top of the frame. In such frames the Potatoes may be planted in February, after starting as before advised, and brought on as fast as the weather and economised sun-heat will permit; or the Potatoes may be forwarded in 5-inch pots, and planted out about the 1st of March. But, when forwarded in this way, say till they are perhaps 6 inches high, they must be kept growing, by close attention to hot linings applied to the sides of the frame, or by shutting up early in the afternoon, so as to make the most of the sun-heat. Water must be given sparingly. Out of such frames we have had excellent crops of Mushrooms from spawn inserted in the soil after the Potatoes were planted; but the success of the Mushrooms depends upon the temperature of the bed being kept up to about 70°, and the sparing supply of water till the Potatoes are got, when the bed should get one or two good waterings with tepid water, which will bring the Mushrooms to the surface if they are there. As the Potato-stems get almost in contact with the glass soon after planting, and are apt to get caught by the frost, care must be taken to cover the sashes with a little of the driest of the litter at night whenever there is danger from frost. A very thin sprinkling of dry straw will keep out more frost than any kind of cloth covering, being one of the best non-conductors. Those who are desirous of making the forced and out-door crops shake hands should forward a quantity in pots or pans, and plant out in a warm south border when they are 4 inches high, about the 1st of April—always having a little dry straw handy in case of frost.

J. S. W.

DATE PLUMS.

THE recent introduction of some new Japanese varieties of Date Plum has given a new interest to the genus *Diospyros* not to be passed over. The notes which follow are the results of actual observation, and may, therefore, be worth putting on record. In the first place, we will say a few words respecting the state of the question both horticulturally and botanically. Until within the last few years there were only three species and a few varieties of *Diospyros* cultivated out-of-doors in European gardens. The commonest, *D. lotus* from the Caucasus, also called the Italian Date Plum, as it is found in a half wild condition in the Italian peninsula, is known by its pleasing habit and yellow fruit, about the size of a Cherry, upon which the thrushes and blackbirds feast in the autumn. Another species is *D. virginiana*, the Virginian Date Plum or Persimmon, as it is called in America, a much larger plant in all its parts. It has handsome shining foliage, and its round orange-yellow fruit is as large as a Green Gage Plum, and edible, though not of a

particularly good flavour. The remaining species, found in nurseries, are, in our opinion, simply varieties of this. In 1789, a third species was introduced from Japan, differing entirely from the two preceding and known in Japan as a fruit tree, under the name of Kaki (*D. Kaki*). This tree will only succeed in the Orange region, where it bears a roundish fruit, as large as a small Apricot, yellow and sugary when ripe, and known under the name of Fignes caques. It is now rather widely dispersed in the south of France. We saw a fine specimen of it in Italy, in the botanic garden at Pisa, and Prof. Caruel, the director, kindly gave us some of its fruit, which has something of the taste of a thoroughly ripe Medlar, but it is more sugary. Things remained thus until about the year 1859, when the Paris Museum of Natural History received a consignment from Mr. E. Simon, in China, which contained a new species of *Diospyros*. The plant grew and flowered, and showed fruit in 1869. At first M. Carrière thought he had the true *D. Kaki*, but soon discovered his error and described the new plant as *D. costata*. Afterwards he attempted to show that the supposed *D. Kaki* cultivated in the South was really a Nepaules species, which he proposed to call *D. Roxburghii*. In reply to this, Mr. Decaisne declared the plant named *costata* by Carrière to be no other than the *D. Schitso* of Bunge. The new tree was propagated under the name of *D. costata*. We possess a fine specimen of it at Lacroix in Touraine, where it grows vigorously, its large shining leaves resembling those of *Magnolia Soulangeana*, and its luxuriant habit rendering it highly ornamental. Its handsome orange fruit, as large as a Peach, ripens towards the end of autumn, and gives it rank as a valuable fruit tree. There are four well marked species of Date Plum which we possess in Europe at the present time. But there are also several badly-defined varieties of North American origin in cultivation. Indeed, they are scarcely worth the trouble of distinguishing, but we may roughly characterise them as follows, from an examination of the living plants in the nursery of Mr. André Leroy, at Angers. What is generally held to be the typical *D. virginiana* is a handsome tree with a spreading crown, flat, acuminate, of glabrous and shining leaves, and a nearly spherical, slightly-depressed fruit, encircled at the base by a large collar formed of the persistent calyx; and, besides this, there are the following varieties:—1. *D. v. insignis*, of very slender habit, with Willow-like foliage. 2. *D. v. pubescens*, described as a species by the botanist Pursh; but, in our opinion, a mere variety having oblong acute leaves, clothed with soft hairs beneath and borne on long petioles. 3. *D. v. angustifolia*, the same as the type, except that it has narrower leaves. 4. *D. v. villosa*, a very remarkable variety, of which the obtuse leaves recall *D. Kaki*, but its fruit is not yet known at Angers. 5. *D. v. purpurea*, a pretty variety, the leaves of which when fully developed change to a purple-red. 6. *D. v. Perquinii*, a beautiful tree with acuminate, shining leaves, closely approaching what we have seen in many other nurseries under the name of *D. calycina*. 7. *D. v. lucida*, the last, which we consider the most valuable of all. It is a slender, graceful tree, with spreading cylindrical smooth ash-grey branches, medium-sized, glabrous and shining, yellow-veined leaves tapering to both ends, and supported on fine petioles. Its abundant sessile fruits are as large as a Green Gage Plum, perfectly spherical, slightly ribbed, surmounted by a cylindrical mucro, surrounded at the base by the accrescent calyx, about an inch broad, and assuming when ripe a beautiful orange colour. It contains a soft sugary pulp when ripe, recalling the flavour of Apricot marmalade and honey. We tasted it in company with Mr. Leroy, and considered it superior to the fruit of all other varieties we had previously tried. Great confusion prevails respecting the application of the names *D. intermedia*, *digyna*, and *stricta*, found in English catalogues of forty years ago, and no faith can be placed in their present use in collections. They are all the issue of *D. virginiana*. The principal object of this notice, says the *Illustration Horticole*, is to induce people to cultivate the better varieties of the Virginian Date Plum. The species was introduced nearly 250 years ago (1629), and it is scarcely known even now. *D. costata* is even superior, but it has the disadvantage of being less hardy, not being able to resist the winters of Paris; it is still very rare, and must continue so for a considerable time, whilst *D. virginiana* is scarcely touched by the frost. In America the latter is esteemed as a fruit tree, under the name of Persimmon. Its blotted fruit is eaten with or without sugar, or made into a preserve, like that of *D. Kaki* in Japan, of which we recently tasted some samples sent to the exhibition at Lyons by Mr. Hénon. It is also employed in making a kind of cider, spirit, and beer, with the addition of hops. Oven-dried they resemble the French Prunes. Were the Date Plum more widely grown in the deep cool soil of our parks and gardens in the south of England, and especially the variety *lucida*, which Mr. Leroy possesses, we should, perhaps, have another handsome tree and another good fruit.

NOTES OF THE WEEK.

— As we write, Bedford Square is undergoing a thorough overhaul. The fine old Pines stand out grandly as the dwindling, mean, under-shrub vegetation, common to Bedford, as to other west-central squares, is being swept away, root and branch, from beneath the trees that are to remain.

— AMONG Orchids to be sold at Stevens' on the 21st inst., is a new *Masdevallia*, named *M. Davisii*, in compliment to its collector, Mr. W. Davis, who discovered it in the Western Cordilleras of South America. Its bright orange flowers are both handsome and effective, and it will form a welcome addition to the scarlet, vermilion, and white-flowered kinds.

— WHITE LILAC, so popular in Parisian markets, has again made its appearance in Covent Garden. It is, as we have before stated, the common purple kind forced in darkness, by which means delicately perfumed pearly-white flowers are obtained, which are largely employed in the composition of bridal and other choice bouquets.

— The Metropolitan Board of Works, who are now the conservators of Clapham Common, in compliance with the wishes of the residents of Clapham, have determined that the Common shall remain intact, and as an open space, free to the public. Some young trees have recently been planted by the roadside, and the Common, already studded with forest trees, will, in time, present a park-like appearance. The ponds of stagnant water are to be purified, and the Common drained, but the intention of converting it into dressed ground is abandoned.

— THE new edition of Gordon's "Pinetum" is, we understand, nearly finished, and will be published early next month. It will contain a hundred pages more than the previous edition, and will be rendered very complete as regards nomenclature, Mr. Bohn having added both English and popular names as well as those under which the different species are known, not only in Japan and China, but also in Germany, France, and Russia. The book is thus fortunate in having both author and publisher fully acquainted with the subject on which it treats.

— MESSRS. ELLWANGER & BARRY, of the Mount Hope Nurseries, Rochester, New York, write to us as follows respecting their finer kinds of Pears and Apples:—This season our finest late Pears ripened earlier than usual owing to the autumn being very warm and dry. The *Beurré d'Anjou* is nearly gone; we have, however, still *Beurré gris d'Hiver*, *Vicar of Winkfield*, *Lawrence*, *Winter Nelis*, and *Josephine de Malines*; the last is our best keeping fine melting Pear. As regards Apples, we have a great crop of *Ribstons*. We think, however, that our best winter Apple in Western New York is the *Northern Spy*. In the winter of 1873-74, when it was yet new, we presented it to our friends in Europe and sent a basket of it to the Queen. The *Newtown Pippin* does not succeed well here; it does better near the sea coast and southward. The *Baldwin* is the great Apple of the market orchard, for profit, all over New York and New England; next come the *Rhode Island Greening* and *Roxburg Russet*. The late Mr. Robert Thompson once told us that the two last-named were better suited to the English taste than any other American Apples. He considered the *Northern Spy* to be the finest Apple he had ever tasted.

— At a recent meeting of the Philadelphia Academy of Natural Sciences, Mr. Thomas Meehan referred to a former communication in which he exhibited specimens of *Euphorbia cordata*, or *E. humistrata*, collected by him in the Rocky Mountains, and which, normally procumbent, had assumed an erect habit on being attacked by a Fungus, *Æcidium Euphorbiæ hypericifolia*. He now found that the common trailing *Euphorbia* of our section, *E. maculata*, when attacked by the same Fungus, assumed the same erect habit. There was an additional interest in this observation, from the fact that, with change of habit of growth there was a whole change in specific character in the direction of *E. hypericifolia*. In a comparison of the leading characters of the two species, we see that in *E. maculata* there is a profusely hairy stem, while that of *E. hypericifolia* is nearly smooth. The same is true of the fruit. The leaves of the former species are very oblique at the base, the latter nearly regular. The flowers are produced in all the axils. In the *E. hypericifolia* the stems have a tendency to be nodose at the joints, while *E. maculata* is nearly free from this character, and the flowers are mainly in heads at the end of the branches. The *E. maculata*, after the fungoid attack, becoming erect, also becomes nodose, and has the flowers on the ends of the comparatively smooth branchlets, while the leaves have lost their pointed obliquity; and, in short, all the characters make an intermediate between the two species. He said it would not be fair to assume, from these facts, that *Euphorbia hypericifolia* was an evolution from *E. maculata*, but,

as there could be no doubt that nutrition was one of the factors in the government of form, we could say that certain phrases of nutrition, brought about by an attack of a minute Fungus, would change the characters in the direction of those in that species.

— THE "Garden Almanack" will be published next week as a supplement to THE GARDEN, and will be presented gratis to subscribers.

— THIS number of THE GARDEN contains the first of a series of articles written by Mr. Thos. Baines, to meet the wants of those who cultivate their own gardens. The "Amateur's Garden" will, henceforward, find a place in our columns every week.

— It is intended to hold at Lyons, next year, an International Exhibition of Potatoes, in connection with the great meeting of the *Cercle Horticole Lyonnais*. The schedule will provide for six classes, and the "premier prix" will be a silver cup, to be awarded to the competitor who shall have produced the largest and finest crop from one tuber. The judges will consider quality and quantity as of equal importance.

— BLENNHEIM ORANGE APPLES, grown this year in an orchard at Perryfield, Godstone, Surrey, weighed, when gathered, 19 and 22 oz. each, and fifty on the same tree were each over 1 lb. Mr. Richardson, the gardener at Perryfield, informs us that the productiveness of the orchard in question is remarkable, the trees every season for twenty years being loaded with fruit, even when scarcely any exists in the neighbourhood. They are planted on a bed of clay in which there are here and there small nodules of ironstone and flint, and are top-dressed every other year with stable-dung. Provide good shelter—an important point—says Mr. Richardson, manure well, and prune every year, and plenty of fruit will be the result.

— OF Clapp's Favourite, a Pear to which we have more than once made favourable allusion, an excellent coloured illustration is given in the last number of the *Bulletin d'Arboriculture*. Sufficient attention has not, hitherto, been given to this variety on account of its being a summer Pear, but it is none the less valuable on that account. Its fruit, which is large, is of a citron-yellow colour, washed with bright red on the sunny side like the *Trout Pear*. The flesh is white, delicate, and juicy. In France, this Pear is stated to have yielded abundant crops, which were fit for gathering in the end of August and beginning of September; and it is considered there to be a good market Pear.

— HORTICULTURE is practically taught throughout France, in the primary and elementary schools. There are at present 28,000 of these schools, each of which has a garden attached to it, and is under the care of a master who can impart a knowledge of the first principles of horticulture. Even in the schools to which no garden is attached the theory of cultivation is taught; but it has recently been decided by the Minister of Public Instruction that the number of school gardens shall be largely increased, and that no one shall be appointed master of an elementary school unless he can prove himself to be capable of giving practical instruction in the culture of the soil. The advantages of this system of practical education can hardly be exaggerated.

— THE Alden process of drying fruit operates by means of an ascending current of heated air, by which a portion of the water contained is evaporated. Some of the starch is changed to sugar, and the fruit rendered sweeter in flavour. This, together with the perfect cleanliness of the process, makes the product desirable, and it readily sells at considerably higher prices than that dried in the ordinary way. According to the *Tribune*, all kinds of fruit and vegetables are susceptible to this treatment. A bushel of Apples yields 6 lbs. of evaporated fruit; a bushel of Peaches, 6 to 8 lbs.; Tomatoes, 3 lbs.; sweet Potatoes, 16 lbs.; Onions, 4 lbs.; two dozen ears of sweet corn, 1 lb., and other fruit in proportion. The process is a patent, and is not, so far as we know, in use in this country.

— M. FAIVRE has recently performed a series of experiments on the Mulberry, Hazel, and Cherry Laurel, which he considers goes far to prove the fact that the substances which supply the food of plants have an ascending motion in the bark. For this purpose he made perfect or imperfect annular incisions through the bark, or detached pieces of the bark to which buds were attached, or removed entire cylinders of bark from the trunk. The result of the experiments was that the buds always continued to develop when the communication remained uninterrupted with the lower portion of the trunk; while, when this communication was completely destroyed, the buds invariably withered away. If the bud was separated by a perfect annular incision, it withered the more slowly the greater its distance from the incision; and in these cases the starch disappeared entirely from the portions of the wood above the incision between it and the bud. When entire cylinders of bark with buds on them were removed, the buds continued to develop, and even produced branches bearing leaves.

THE INDOOR GARDEN.

ORCHIDS WITHOUT ORCHID HOUSES.

How is it that Orchids are not more generally grown? It cannot be that they are too expensive, since the rarer stove-plants and Ferns are equally as costly to purchase in the first instance; but many think that Orchids are not only difficult plants to grow satisfactorily; but, in addition, that they require houses specially constructed for them. This is an old idea which, somehow or other, originated when Orchids were first introduced into this country, and it does not seem to have been exploded. Yet, notwithstanding all that Williams, Warner, Anderson, Culley, Hill, Sorley, Bullen, and a score of other good cultivators have taught us, not only with the pen, but in their everyday practice, we have, during our visits to many of the gardens in this country, repeatedly met with Orchids growing well in stoves, greenhouses, Vineries, Pine-stoves, and even in pits and frames—indeed Mr. James Anderson used to grow his fine plants of *Masdevallia* and *Odontoglossums* in an ordinary brick pit just like so many *Pelargoniums*, and in few collections that we have seen were the plants so strong and vigorous as these. A greenhouse temperature is amply sufficient for many of the beautiful Orchids from the highlands and mountain slopes of India and the New World, but it is highly necessary that the atmosphere of the house should contain much more moisture than is in general given to ordinary greenhouse plants. We have often thought that it is for want of moisture in the air and at the root, that in Orchid culture often fails. They are essentially moisture-loving plants, and, if not amply supplied, they soon show signs of ill health, and eventually succumb. It is impossible to water *Odontoglossums*, *Disas*, *Masdevallias*, and the cool-growing Peruvian Orchids too much, summer or winter, provided that the compost in which they are potted is fresh and well-drained. This is an important fact that all growers will do well to bear in mind, as well as the necessity for inducing *Sphagnum* Moss to grow freely on the surface of the compost. Few Orchids fail to luxuriate in a compost on which this Moss grows well, and it exerts a beneficial influence by keeping the roots in a uniform state of moisture. Any low span-roof lean-to house or pit may be used as an Orchid-house with success, if heated so as to keep up a mean winter temperature of 50° , that is 45° as the minimum and 55° as the maximum temperature. Even if the temperature sinks to 40° no harm will be done, provided that a humid atmosphere is preserved. One very particular point in the culture of *Odontoglossums*, cool Orchids, *Disas*, and *Masdevallias* is, that their rest is not so decided as in the case of *Dendrobies* and *Cattleyas*. This being the case, it follows that a uniformly humid atmosphere must be maintained, together with a free supply at the root. The compost itself is a great essential in the successful cultivation of temperate Orchids, and should be of such a character as only to hold a certain quantity of moisture, no matter how much is supplied from the watering pot. To ensure this, the pots used must be clean, and at least half full of crocks or drainage. Fibrous peat and living *Sphagnum* Moss, with about one-fifth of thoroughly dried horse-droppings, make an excellent general compost for nearly all cool-growing Orchids; and sufficient coarse well-washed sand, or sandstone grit, to keep the whole in an open or porous state, must be used. The ordinary fine white sand in general use is much too fine for these plants, and should never be used if coarser materials can be obtained. Elevate the pseudo-bulbs of the plant a little above the rim of the pot, so as to allow all superfluous water to drain away freely from the base of the plant and the young growth. If these essentials are duly carried out, cool-grown Orchids will be found as amenable to culture as tender Ferns or tropical stove plants, and are, perhaps, even more beautiful and interesting, and the amateur who attempts their culture because he is fond of the plants, is sure to succeed. Select some robust-constituted, strong-growing species to commence with, such as *Cypripedium insignis*, *Dendrobium nobile*, *Odontoglossum grande*, or *O. Alexandra*, and, if these succeed to your liking, then add others according to taste and the space at your disposal.

F. W. B.

BEGONIA FUCHSIOIDES.

SOME say that this *Begonia* rarely flowers well until the second year of its growth. By the following system of management, however, good blooming plants of it may be obtained the first year. About the middle of next month take off cuttings, insert them in equal parts of peat and sand, and plunge them in a good bottom-heat, with a bell-glass over them. In about three weeks they will be well rooted. Then pot them off into 5-inch pots, and place them again in a little bottom-heat, where they can have a moist atmosphere. In such a situation they will grow rapidly. Never allow them to become pot-bound. The soil I use is three parts strong maiden loam, two parts Mashroom-bed dung, and one part sand, with plenty of rough charcoal intermixed. In this they grow like Willows. By July or August we have had plants 6 feet high and 3 feet through, covered with scarlet flowers. While in their growing state the shoots should be kept pinched in, which prevents them getting too gross and woody. They push out laterals plentifully, and from August till Christmas, and even after that, they will be one mass of bloom. Up to August they may be grown in a stove, and afterwards moved to the conservatory. Some recommend stunting them in small pots to make them bloom, but that process destroys the beauty of the foliage, and causes them to produce puny flowers. The pot in which they are to flower should be about 20 inches deep by 19 inches wide, and if grown properly they will require all that room. Never allow them to want water, of which they absorb so much in summer, or they will turn yellow. Being gross feeders, you may water them with soot-water, or manure-water, in the proportion of 3 quarts to a 4-gallon can. If this is rightly followed out, you will be doubly paid for all your trouble, and that, too, during the first year. After they have done blooming, remove them to the stove, where they will soon begin to grow again; but in order to keep up a stock of fine healthy plants, I would recommend them to be struck from cuttings every year, and treated in the manner I have just described. J. R.

Tunbridge Wells.

Jalap Plants.—In THE GARDEN of December 5th, you ask if *Convolvulus Jalapa* is in cultivation in this country, and if it has been found hardy? There is a plant of it in the Botanic Gardens at Liverpool, where it has been for the last fourteen or fifteen years, growing on a bed of gravel, the roots being about the size and shape of the double *Cocoa-nut*. I do not think it has ever been tried in the open ground; perhaps the curator (Mr. J. Richardson), will possibly act on the suggestion, and give it a trial, and report the result in your columns. *Exogonium Parga* matured seeds with me this season for the first time; these are now in the hands of Mr. Thompson, of Ipswich, and I have no doubt that it has done so, and much more freely, in the College Botanic Gardens at Dublin, where both Mr. Ellacombe's and my own plants originally came from, nine or ten years ago. Both the *Jalap* and the *Scamony* grow luxuriantly, with me, and I originally intended to recommend their cultivation on a large scale in this country for medicinal purposes, but I find that although they grow freely, and produce, like the common *Bindweed*, abundance of fleshy root-stems, from which they may be readily increased, they produce but slowly the tuberous roots from which the active property is extracted, and those are very deficient in resin, compared with prime imported samples. Judging from my short experience, it would require from four to six years to fully mature a crop, and would render it impossible in this country.—J. TYERMAN, *Torquay*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

***Phalenopsis grandiflora*.**—A plant of this has just opened its flowers here, one of which measures 3½ inches in breadth. The lip is 1 inch, the stalk is 2½ inches in length and is furnished with nine flower-buds. Is not this extraordinary? My gardener attributes it to the plant being suspended immediately over a tank where it is exposed to what is an almost perpetual steaming.—G. W. Cox, *Mount Mount, Hendon*. [A plant of this species in the Orchid house at Kew recently bore flowers equally large.]

***Vellozia corulescens*.**—I have just ascertained from Kew (where I sent the flower of the plant sent to me from Ghent as *Vellozia corulescens*) that my plant is not a *Vellozia* at all, but *Barbarea purpurea*, a member of a family closely allied to the *Vellozia*, and indigenous to the countries from which they come. The *Barbarea purpurea* is well figured in Paxton's "Magazine of Botany," Vol. XII., page 27, and in the *Botanical Magazine*, Vol. LIV., t. 2, 777.—W. E. GEMBLETON.

The Bull Palm in the Royal Botanic Gardens, Edinburgh.—This Palm is stated by Mr. McNab to be about sixty years old. It stands 36 feet high from the surface of the floor, and has a clean upright stem 1½ feet in height, the circumference at the base being 5 feet 4 inches, and 3 feet at the top where the leaves begin. At present the leaves are forty in number—the side ones, including the leaf-stalk, being about 16 feet long. The head of the Palm is somewhat of a globular shape, 22 feet in diameter, and is covered with large clusters of fruit.

THE GARDEN IN THE HOUSE.

CHRISTMAS DECORATIONS.

At Christmas, decorations of some kind are, as a rule, attempted in every house; indeed, one could hardly believe it was Christmas in the absence of Holly, Ivy, and Mistletoe,

which have so long at that season occupied prominent places in our households. The custom of decorating with evergreens is far from being a modern one. The Romans, 2,000 years ago, did the same thing; indeed it is more than probable that the origin of adorning our homes with Ivy, Holly, and Bay, must be sought for in the Roman Saturnalia, held every year towards the end of December. Formerly the decorations of rooms consisted of a few branches of evergreens stuck here and there as might be convenient; but now they are of a much more complicated character, and require time and skill in their manufacture. Where decorations of any extent are annually employed, the week before Christmas is a busy time with the ladies of the household, as the making of the decorations principally falls to their share.

To make effective and pretty designs requires good taste, practice, skill, and a general knowledge of the materials to be employed. A few hints, on this subject, therefore, may prove acceptable, as I have assisted in making many decorations at Christmas time, and so can speak from experience. First come under our notice the shrubs to be selected; though Holly, Ivy, and Mistletoe are principally used, there are many other materials which may be enumerated, and which are admirably adapted to intersperse with the above so as to relieve that sameness which would occur were Holly and other ordinary Christmas evergreens only employed. Amongst others I may mention the following:—Arbutus, Aucuba, Bay, Euonymus, Gold and Silver Hollies, Ives of different colours, Laurels, Laurustinus, Portugal Laurel, Spruce and Silver Firs, Yew, &c.; also branchlets

of Arbor-vitæ, Cypress, Deodar, Juniper, Thuja, or any other ornamental shrubs obtainable. Having said so much for evergreens, let us advert to the foundations on which they are to be worked. These consist of the following, for, according to the style of decoration, so the foundation must be selected. For garlands, wire or strong cord should be used; the latter is, however, preferable, as it is not so liable to twist as wire; and, for what are called upright wreaths or panels, fine iron rods are the best. For ornamental devices perforated zinc should be used; for letters, strong brown paper; for narrow beadings, where single leaves only are employed, tape wire; for crosses, picture frames, texts, &c., flat laths, such as are used in the construction of ceilings by plasterers, or Hazel rods; and for wreaths strong wire; for small garlands fine twine is serviceable. In addition to the above, several balls of hemp twine (fine and coarse), large needles and strong linen thread (dark green or black), a pair of scissors, penknife, and reels of binding wire, must also be at hand; and, though last on the list, one of the most important things to be supplied with is a strong pair of kid gloves to protect the hands from the scratches and cuts which

they are certain to receive if unprotected from the prickly leaves of Holly or from the binding wire. Although I recommend strong kid gloves, I do not mean them to be thick or in any way clumsy, as, if that were the case, it would be impossible to do any of the fine work, such as letters in single leaves, neatly. Having thus alluded to the different materials required, let me now direct attention to the manner in which particular designs are manufactured.

Garlands.—As has been stated, the best material for the foundation of these is strong hemp cord; a loop should be made on one end, and this slipped over a nail or hook, fastened for the purpose in a wooden table or in anything that will hold it firmly. Having a supply of evergreens at hand, cut

to the required lengths, bind them on to the cord with fine twine; one firm twist of twine will be enough to keep each bunch of evergreens in its place, and so work down the cord to whatever length may be required. A beginner will find it difficult to keep the garland even as it is being worked; but if such be found to be the case, where it is too full, the pieces can be thinned out with a pair of scissors. If it is desired to

suspend a garland of large dimensions at any height, the following shrubs will be found the best adapted for its construction, viz.:—Arbutus, Euonymus (common), Holly, Ivy, Laurel, Portugal Laurel, Spruce and Silver Firs, and Yew. For giving colour, of course scarlet berries are indispensable, and first amongst these ranks the Holly; but as the berries of the Holly are not plentiful every season, it may be well to enumerate a few others which can be substituted. There is the Arbutus, its lovely berries looking in the distance like little clusters of Siberian Crabs; and the burst seed-pods of the Gladwin, which have taken such a prominent place of late in florists' windows. The latter can be purchased in town by the bunch for a very small sum, while those who live in such counties as Devon, Somerset, and Dorset can obtain as many as they require by simply cutting them in the hedge-rows or

on the cliffs, as the Gladwin is to be met with growing plentifully in a wild state in those counties. When the berries of this plant are employed, they must be worked in with the evergreens at equal distances, as the formation of the garland is proceeded with; but the best way to arrange the Holly berries is to remove all the leaves and cut off the stems, leaving that portion only which is covered with berries;

a piece of fine binding wire can then be fastened round the stem and passed round the garland, and, where fastened, hid amongst the foliage. In this manner, all the berries can be added after the garland is made. Some introduce flowers made of coloured tissue paper, but I myself prefer colour being given with berries only. Small and light-looking garlands for suspending from gas brackets, &c.,

can be made on fine twine, in a similar manner to those before described; but for this purpose very small-leaved plants should be employed, such as the Prickly Holly, variegated Box, &c.

Upright Wreaths or Beadings.—These are best made on fine iron rods, and their manufacture is very similar to that of garlands, save that the beadings are made on one face, and for binding them, reel wire should be substituted for twine. For

Ivy, Yew, Holly leaves and berries.

Yew, Ivy, Aucuba, Holly leaves and berries.

Ivy, Yew, Holly leaves and berries.

this style of decoration I like to see branchlets of the dark green Holly only employed, its rich glistening dark green leaves being relieved by large bunches of the brilliant berries fastened on with wire, as I have before described, at equal distances apart. Wreaths of very pretty appearance can be made on strong wire for hall lamps, &c., by taking a piece of wire and forming it into a circle of whatever size may be required; on this bind the evergreens with fine wire, using plenty of berries in their construction; blooms of *Laurustinus* also work in well for this purpose.

Ornamental Devices.—These should have their foundations of perforated zinc, cut out into whatever design may be selected. The foundations of the three accompanying illustrations on this subject are supposed to be so formed, otherwise it would be impossible to make them as represented in the engravings. Two of the illustrations represent devices suitable for running round the top of the wall in sitting rooms, above the picture rods, and against the cornice, or round the door frame. The third or circular design is for hanging against any blank wall, or space between pictures, &c. As will be seen in the first illustration, the half circles are formed of a double row of single Holly leaves, these are fastened on by means of a needle and strong dark green or black thread, the needle being passed up and down through the holes in the zinc. In sewing on the leaves only one long stitch in each leaf is required, and the thread should pass along the mid-rib of the leaf, as in this manner it will not be observed. The branchlets of Yew are also sewn on, but more stitches must be employed on account of the length of the branchlets. The variegated Ivy is also sewn on, but each leaf of this plant requires three stitches to keep it open and firm in its position. Indeed, everything employed in the construction of the three accompanying illustrations is fastened in this manner save the berries. The evergreens employed in the circular design are as follows:—The circle is of Yew, the Holly leaves which project are of the silver variety, the Ivy leaves on the Yew circle are also almost perfectly white, a large bunch of Holly berries being fastened in the centre of each cluster. The star is formed of leaves of *Aucuba japonica*, the centre being a tuft of white Ivy leaves with scarlet berries. All the Holly and Ivy employed in the construction of the designs here represented are of variegated varieties, as these are best adapted for placing in conjunction with Yew.

Mottoes Formed of Letters Made of Evergreens.—These are often employed amongst other styles of decoration. If of evergreens, the best leaves for this purpose are the Holly, as sharper outlines can be obtained with this than any other plant, the dark green or variegated varieties being selected according to taste. Whatever letters are required should be cut out in strong brown wrapping paper, and then the leaves sewn on these foundations; letters of white, for placing on coloured grounds, can be formed of Rice by cutting out the letters in white paper instead of brown, brushing them over with liquid gum, and then covering them with grains of Rice. Narrow beadings of single leaves are best made on black tape wire, each leaf being sewn on as before described. Beadings of this description look most effectively round door panels, &c.

Crosses.—These should be made on foundations formed of flat laths, and if these be not obtainable, Hazel rods must suffice; unless a cross be of very large dimensions, small-leaved plants should be employed as far as possible, and the lighter the colours are, if plenty of berries be used, the prettier will be the effect produced.

Picture Frames and Texts.—These can be made on laths in the same manner as crosses, but the Oxford shape when finished, will be found by far the prettiest. If the evergreens selected be of dark colours they should be relieved at each corner by a tuft of light leaves and scarlet berries. Where it is not possible to fasten these frames over those which encase the pictures, they may be suspended by a very slight wire and allowed to hang immediately over the ornamental or gilt ones.

All such decorations as I have just described may have their effect enhanced by being made to look as if frosted. This effect can be produced in the following manner. The leaves should be brushed over with gum in a liquid state, and then dusted over with glass dust from the glass works, which can be

obtained at a very small cost. A mirror draped with long tendrils and sprays of Ivy only, sprinkled with fragments of ground glass, as I have described, has a most charming effect. Many use dried flowers, such as Everlastings in these decorations, but I cannot say I admire them; if a very short supply of berries be at hand, one is sometimes forced to use artificial ones, but if anything artificial can be dispensed with so much the better. Letters can be made in rustic forms with branchlets of Yew, which, if well frosted, are most effective on a crimson or coloured groundwork of any description. As to the placing of our old friend the Mistletoe, that must be arranged according to circumstances, and as may be most convenient. In conclusion, a few remarks may be made on decorations composed of flowers. Across the back of the mantelpiece a small band of flowers may be formed on a lath, in the same manner as in the construction of crosses, save that in the place of branchlets of evergreens, Moss and flowers are substituted. The band or foundation being of green, alternate tufts of scarlet Geraniums and white Primulas look very effectively; a few Fern fronds can also be introduced if desired. Should the flowers I have named be deemed too expensive, Primroses and Violets could be used. Over the buffet a flat or one-sided bouquet could be placed—a large Arum bloom in the centre, and the rest composed of any scarlet and white or pink and white flowers that may be obtainable. I have now given descriptions of those kinds of Christmas decorations I can at the present moment remember as having seen made with an effective result. They are sufficiently numerous, at all events, to make any room look bright and suggestive of the season in honour of which it is decorated.

A. HASSARD.

ROOM PLANTS AND POT COVERS.

AMONG the many receptacles that have been named for concealing the pots of room plants, I do not observe baskets. After trying many plans, we have found nothing so good as baskets of close texture, painted, and varnished a warm brown (I believe called japanning), a colour which detracts from nothing, and harmonises with everything, the brown earth and green vegetation being a safe example to follow. We send pots of the various sizes used to the Blind Asylum, and there the baskets are made to fit them; they have stont wooden bottoms, as the weight of the plant is too great for basket-work. When not required they fit one within another, and take up very little room. The varnish prevents the adherence of dust and dirt. Fresh Moss is laid on to cover the surface of the pots. Our large baskets for groups of plants $7\frac{1}{2}$ to 10 feet in circumference are made of open basket-work, and are lined with Moss; and here let me remark that some of the species of *Hypnum* are the best in the long run for this purpose; though there are many Mosses more beautiful, but they do not last so long. The *Hypnums* grow on dykes or loose stone walls, and also on the exposed roots and trunks of trees, and come off in fine large flakes, very suitable for linings. It seems to be generally forgotten (as also with Sea-weeds), that Mosses are complete plants, with roots and seeds, and that it is in vain to expect such species as are plucked up from among Grass, or scratched off the soil, to last long. By having two lots of the *Hypnum* it can be changed weekly, and if spread on the floor of the potting shed, and well watered, it is wonderful how revived and refreshed it becomes for the next week's use. By collecting it off stone dykes there is less danger of introducing what Cowper calls "visitors unwelcome, into scenes sacred to neatness and repose;" and the "necessary act," which "incurs no blame," is avoided of destroying centipedes, wood lice, beetles, deceptive spiders (with legs folded up and feigning death), small worms, clusters of snail's eggs, and larvae of all sorts, which congregate under the Moss on the bark of trees. In summer, when all Mosses are, so to speak, out of season, we find a good substitute for our linings in turf; first mowing it close, and then cutting it into strips, long enough to go round the inside of the basket. The Grass grows in a couple of days, and looks very well, peeping through the basket work. If we were within reach of a hill, or "links," where fine turf was to be got, with such plants as *Polygala*, *Tormentilla*, *Thyme*, *Cistus*, *Galium*, *Euphrasia*, *Linum*, all flowering amongst it, a charming addition to the plant basket would be the result; as it is, we must be content with our roadside turf, drawing out Dandelions and Plantains, and being satisfied with a Daisy or two. Having a large stock of Saxifrages and Sedums for winter carpeting, we are using them this winter, when our supply of country Moss fails. Long sods of grey Sedum, and green Saxifrage mixed, and the gold-tipped *S. acre*, will, by February, be in good order for producing variety. The effect is very good, and they, like

the Grass, grow, and do not merely keep alive, as does the Moss. For room-plants in winter there are a few hardy ones which we find useful in saving stove-plants which suffer from the extremes of temperature of the room. *Carex japonica variegata*, for instance, has quite the character of *Pandanus gramineus*, or the small-leaved *Dracana gracilis*; by having it for a short time in a stove, as I saw they had at Methuen's Nursery, it acquires a delicate appearance, which, in the opinion of some, gives it an additional value. The green and variegated *Ophiopogon* and *Reineckia carnea*, are also useful, and do not suffer from a sudden fall of the thermometer. The leaves of all droop over the edge of the basket among the small-leaved *Ivies* and *Vincas*, which, to save room, we do not have in pots, but tied in Moss, when they slip into any vacant spot. *Veronica Andersonii variegata* (gold and silver), is another very ornamental plant; it, however, is impatient of the dry air of a room, and, is, therefore, more suitable as a single plant, which can be removed, and watered if need be, without burrowing in the Moss, and distributing the mixed group in a large basket. *Ficus diversifolia* I still never meet with. It is a most interesting, distinct, and invaluable room-plant for summer; we do not risk it in our cold rooms in the winter, as I fear it might cast its small yellowish fruits with which every branch is laden throughout the year; but its thick, leathery, peculiar leaves would stand as well as *F. elastica*, I have no doubt, if the plant was thoroughly hardened off. I hope to send shortly a photograph of our stock plant, in its drawing-room basket. I fancy these plain brown baskets, do not attract the eye from the plants—the first point to be considered, in my opinion, in any arrangement, either in the garden or house, or with cut flowers. To enhance the beauty of one plant by contrasting or combining its form, or colour, with others, is a safe and legitimate attempt; and we see such pleasing effects every day, in the fortunate grouping or position of trees in the landscape (too seldom by any design of the planter) down to the Mosses and Lichens, grouped on the trunks of these trees. But when man's inventions in the way of stone and lime, statuary, rockery, gold and silver vases, Majolica ware dishes, elaborate wire baskets, and glasses of fantastic forms, are attempted, then the difficulty is so great, that nine out of ten fail; and the tenth will be a very questionable success in the eyes of the true lover of plants and honest student of Nature. F. J. HOPE.

Wardie Lodge, Edinburgh.

CULTIVATION IN JAPAN.

By the Hon. HORACE CAPRON.

THE rigid adherence to the most ancient modes of cultivation in Japan, the incomparable cheapness of labour, the thorough character of the tillage, the economy and application of fertilisers, the extent and completeness of the system of irrigation (which utilises the whole water-system of the empire), and the high and continued fertility of the soil after thousands of years of successive croppings, are all of the highest interest to the cultivator. A general knowledge of the character of the soil and climate of any country is a condition which precedes an intelligent comprehension of its agriculture. Those islands of the Japanese group which are settled are situated between the parallels of 32° and 42° north latitude. Agriculture in Japan, therefore, occupies the same parallels of latitude that it does in the United States, that is, from the latitude of the capes of Florida on the south to the latitude of the British boundary on the north. The largest and most central island—Nippon—of which this article will treat chiefly, has a latitude which would give it a mild temperate climate, but there are other influences which are perhaps even more powerful than that of mere latitude. The modifying effect of surrounding bodies of water upon the climate of islands and narrow peninsulas is well understood. It renders the winters comparatively warmer and the summers cooler, as, for example, the islands of Great Britain, and the state of Michigan in the United States. So here, from the narrowness of these islands, the surrounding bodies of water equalise the temperature of every part of them. As in the case of Great Britain, there is the additional and more powerful influence of streams of thermal waters, like the Gulf Stream, which wash both the eastern and western shores of the Japanese group. This warm "river in the ocean" takes its rise under the tropical sun, far south, and runs north along both the east and west shores to their northern junction. From whatever direction the currents of air come inland they bear the warm breath of these thousand streams fresh from the Spice Islands of the Indian Ocean, through the inland valleys, over the hills and high up the mountain sides, moderating the heat of summer and tempering the cold of winter, till all the seasons become almost one perennial spring. The bluffs, hills, and mountains in every part of the islands are covered with forests of Pine, Cedar, Fir, Cypress, Beech, Birch, Maple, Oak, Bamboo, Palm, and, in fact, with every variety of tree or shrub known in the temperate and tropical climates, which meet and blend so perfectly here

that their influence upon the climate and rainfall must not be overlooked. In this connection it may be proper to say that these uncivilised people, as they are called, have adopted a policy the very converse of that followed in America and Europe in relation to these protecting coverings of Nature. The Japanese government has preserved their forests, and in fact ensured their increase. No license to cut down a tree is granted, except upon the condition that three more shall be planted and grown in its stead.

Temperature and Rainfall.

The utmost range of the mercury during the year 1873 at Yeddo (latitude of Raleigh, N. C.) was 65° F. The hottest day of the summer was 91°, and the coldest night of the winter was 26° above zero. Only two or three times did the mercury touch 32°, the point of frost. The mean temperature for the winter months is 45°, of the spring months 56°, of the summer months 75°-50, and of the autumn months 64°. The mean annual temperature, therefore, is 60°. This is a remarkable mean, when we consider that in the heat of mid-summer the mercury only rises to 90°, and in the winter seldom goes as low as the freezing point. December shows the highest temperature of the winter months, having a mean of 48°-75. January and February have had the same temperature for the past ten years, the mean of both having been 42°. The climate for these three months has, in addition to its mildness, the advantage of being dry, as the reader will see when I come to speak of the rainfall. March is 4° warmer than February, having a mean temperature of 46°. April is the first real spring month, being 12° warmer than March, and having a mean of 58°. June has a mean of 68°, and July of 78°. August maintains her universal reputation of being the hottest month by having a temperature of 81°. The extreme mildness of the winter months is best illustrated by the fact that the tillage and growth of a great variety of vegetation goes on the same as in summer, and the fields are as green as during spring. Thus comes the universal practice, unknown to our culture, of following the harvesting of one kind of crop immediately by the planting of another kind on the same ground. Cultivation has no winter of rest and inactivity here. The husbandman sows, and tills, and reaps through all the seasons, year after year, of his life. Every month has its planting-time for some kind of vegetation, and its harvest for others, generally of the simplest kinds of food-products. It is these climatic influences, together with a perfect system of irrigation, high cultivation of the soil, augmented by the application of every available material which will increase its fertility, gathered with scrupulous care and applied with a lavish hand, that enable the farmers of Japan, without foreign aid, and with half its agricultural capabilities untouched, to supply its dense population of over 33,000,000 of people. Japan has a rainfall as great, and in some localities greater, than that of Oregon and Alabama, which have by far the greatest precipitation of moisture in the United States. In Japan the annual rainfall along the seashore is 58 inches. In the interior, at the foot of the mountain ranges, the fall is much greater, in some places amounting to 75 inches. The warm months are the rainy ones. The winter has little rain, less than 2 inches per month; the spring from 10 to 15 inches of rain; the summer months from 20 to 25 inches; and the autumn months from 18 to 20 inches. Such a mild temperature through the whole year, with such a great amount of moisture, gives every portion of the empire a luxuriant growth of vegetation, unknown in the United States, except, perhaps, in the cane-brakes of Louisiana and Florida. All the valleys, bluffs, hills, and mountain sides are covered with a dense growth of tall coarse Grass. There are no barren lands. On the Hakoni range of mountains—the highest range in Japan—at an elevation of nearly 9,000 feet above the sea-level, the highest peaks grow a coarse Grass, from 3 to 4 feet high. Such an amount of vegetation, growing annually and going to decay, has formed a black vegetable soil from 4 to 8 feet deep. The whole surface of the country is uneven; there are high hills and bluffs everywhere; and lying between them there are deep and often narrow valleys.

Soil and Water.

The whole country is of volcanic origin, and, underlying this black vegetable mould, and more or less mixed with it, the whole geological formation is rich in all these saline and alkaline materials with which volcanic formation abound. The hills and bluffs are volcanic upheavals, and the deep narrow valleys were once merely arms of the sea; but in time the *débris* from the outpouring of the volcanoes, and the weathering of the formation of the upheaved bluffs and hills, gradually filled up these intervening spaces, and the waters retiring, these valleys were formed. Since that unknown time, through silent centuries, the disintegrating of the rocks and the luxuriant vegetation on the hills and bluffs have been carried into these valleys, till now the soil is in many, if not most of them, 20 to 30, and in some even 40, feet deep. From the main mountain ranges,

some of which have an average elevation of 8,000 feet, large rivers take their rise, often so wide and deep as to be navigable for miles from their mouths. The lower hills and bluffs give rise to smaller streams, which thoroughly water the whole country. Springs abound everywhere, and wells with pure cool water can be had by digging from 6 to 18 feet from the surface. With their great rainfall, three times as great as the average of the United States, and with their abundance of living streams and springs, the people have found irrigation so useful and beneficial that they have constructed a vast and universal system of irrigation by immense labour. Reservoirs have been built everywhere on the higher grounds, from which a perfect network of great and small canals radiates to all the tilled land. The system of irrigation known to us as practised by the Moors in Spain, by the Aztecs in Mexico and Peru, and by the ancients in Egypt and India, was confined to limited districts; here it is in every valley and on every hillside, and is as old as their occupation of the islands. What a lesson is there here for cultivators. With only one-third of their rain, with a country comparatively easy to irrigate, and with such an inland water system as is unknown elsewhere, we allow immeasurable volumes of water to be carried to the ocean unused year after year, while our crops fall each season far short of the possibilities of the soil, and fail almost entirely as often as every seventh year. Faulty as the Japanese land system is, in many respects it ensures thorough tillage. The title to the soil is retained by the government, and the land is leased for a term of ten years, with a privilege of renewing perpetually on the condition of thorough cultivation; failing in these conditions, the lease is cancelled and a good farmer sought for. Cultivators as a class in feudal Japan were next in rank to the "men-at-arms." They were the second class in the empire, the manufacturers, artisans, and merchants being socially far below them. Although this high rank imposed many onerous duties, it was of the greatest benefit to them. As landed gentry they had important privileges, and they were universally educated. They were able to employ the best talent to teach their children. Promotion from their class to that of the men-at-arms was not frequent but it was possible. The high rank of the farmers under this system had much to do with the high character of agriculture which grew up under the feudal rule.

Labour.

Labour is cheap and abundant in all parts of the empire. Since the opening of the ports to foreign trade, and the commencement of exportation, prices of agricultural products have been enhanced and labour has risen in proportion; especially is this true around the open ports, where the native labour has come into competition with foreign. The labourer's food is of the simplest kind, and is proportionately cheap. They eat boiled Rice, boiled Wheat, boiled Barley, and a variety of vegetables (generally Turnips) boiled and mixed with the Rice, Barley, or Wheat. They may be able to afford fish once or twice a month for a holiday-feast, but if so, it is of a cheap poor kind. It may be said that their diet is exclusively vegetable; they never eat animal food, or fowls, or eggs—yet they are always fat, stout, and hearty. They labour at all times of the year in the field, men and women together, almost, if not quite, as naked as they were born. They are muscular, active, and skilful, quiet, honest, and faithful. Little as the compensation of these labourers is, and simple and even meagre as their food may seem, they are not the over-worked and poverty-stricken class that may be found in some parts of Europe. The eight-hour system has been practised in Japan for centuries. There is an endless number of holidays also. The 1st, 6th, 11th, 16th, 21st, and 26th of each month are invariably holidays. Then the more important food crops have their harvest holiday or days, and there are religious holidays and Government holidays. All these are celebrated by gatherings in towns and villages, temples and groves. There is music, and there are brilliant decorations of flags and lanterns, and there is singing and dancing, and these labourers are jolly and happy. They sing as they dig, sow, and hoe; they sing going to toil, and they sing returning from it. Such is the soil, such the climate, and such the natural advantages of Japan for agriculture. No wonder, then, that without a foreign market for their surplus products, even without the stimulus of competitive intercourse with the world, agriculture has flourished and become the leading industry. It could not be otherwise, for nowhere on the green earth under the sun had Mother Nature been so prodigal of her choicest gifts to the husbandman. There are about 30,000,000 acres under tillage in the empire. Every inch of these 30,000,000 acres is under the most complete and thorough cultivation. If the reader has ever seen the culture of the gardens in the neighbourhood of great cities, he can have a just conception of the appearance of the farm-land in Japan. The whole cultivated portion is a garden. Two-thirds of the entire area cultivated grows both summer and winter crops. The implement that stirs the soil is either a spado

or hoe, which loosens it to the depth of from 12 to 15 inches. A rude plough is sometimes used, but it is mostly drawn by hand. The implements are the same as were in use a thousand years ago, and the modes of cultivation have remained the same through all that time.

Fruits

of some kinds are grown in all parts of the empire. The soil and climate are especially adapted to the growth of semi-tropical fruits. The former exclusiveness of Japan prevented the introduction of the better varieties. Isolated as they were, they contented themselves with half a dozen inferior varieties. Oranges, Limes, Lemons, Grapes, Persimmons, Pears, and some Blackberries, all very inferior (excepting one variety of Orange and one of Grape), were all they had. They have wonderful skill in dwarfing fruit-trees. All kinds are dwarfed without diminishing the size of the fruit. I think our fruit growers could learn much from the Japanese in this matter. I have seen acres of Pear-trees not more than 4 to 6 feet high. These trees were set out in rows, about the same distance intervening. At the height they want the trees to grow, say 4 or 6 feet, a lattice-work of small Bamboo poles is built over the whole orchard. As soon as the shoots of the Pear tree grow to this lattice, they are trained to run along it horizontally, and are confined to the poles by hempen strings. When first seen it looks like a Grapery. The wind cannot shake the trees to disturb either the flowers or the fruits. The most perfect system of training and control over the new growth is in use, so that the sap of the tree, instead of being consumed in the production of a superabundant growth of new shoots, is directed to the growth and perfection of the fruit. When the new fruits now being introduced into Japan by the Kaitakushi department are disseminated everywhere, Japan will become one of the finest fruit countries in the world. All that is wanting will then be supplied. They have soil, climate, and skill in dwarfing and training far superior to that of any other country. The same may be said of the cultivation of vegetables, which are very inferior. Of the Mulberry tree and Tea plant I shall not write, they having received full attention from others. Of grazing, I will only say that, with a population of 33,500,000 millions, there are only 300,000 horses, and 70,000 head of horned cattle, and no sheep. The grazing area on the bluffs, hill, and mountain sides of Japan, unoccupied for any other purpose, is greater than the grazing area of all the British Islands and Ireland. The attention of the Japanese government is being attracted to this important subject, and it will not be long till this great resource will be utilised.

I cannot close this article without again referring to the system of irrigation, which enables these people to realise the highest possibilities of the soil, in all seasons, with all kinds of crops. Their system of ditches is so arranged as to act as an equaliser of moisture; if it is a dry season they supply the deficiency from the reservoirs; if it is an excessively wet season they drain away the surplus moisture. It is a matter well worth all the attention we can bestow upon it. The Japanese system of fertilising is just as admirable. In the whole empire not one particle of material that can be used to fertilise the soil goes to waste; all the Grass of the bluffs and the straw of the Rice, Barley, and Wheat is saved; all the droppings on the streets and highways are carefully gathered. The refuse from the extensive fisheries is utilised, and Sea-weed is gathered in great quantities and used. In all the towns, villages, and cities the manure of the closets is entirely saved and applied to the surrounding lands. In the city of Yeddo alone millions of dollars' worth of fertilising material is saved, which, with us, would be lost to agriculture. The savings from the closets of 33,500,000 of people has an important influence upon the agriculture of Japan, and the economy of this fertilising element, which we lose in the United States, is the most important of all. The whole area of the settled portion of the Japanese Islands is not much larger than the New England States. Upon this is concentrated a population nearly as great as that of the whole United States. With thrift, economy, and skill in agriculture, but without live-stock to convert the luxuriant vegetation of the unoccupied land into manure for their tilled fields, or any system of rotation of crops supplemented, as with us, by the renovating Clovers, and unaided by mechanical appliances of any sort, the Japanese farmer produces annually from one acre of land the crops which require four seasons under their system in the United States. Thus the food of this vast population is supplied without the importation of a single article, and still not one-half of the land is under tillage. The grand secret is, drainage, irrigation, economy and application of fertilisers, and thorough tillage.

We take the above from a report of the United States Commissioner of Agriculture on Japan. It is so interesting that it leads to the desire that some competent person would supply us with a good account of the remarkable horticulture of that country.

THE FLOWER GARDEN.

THE ROSE MALLOWS.

(HIBISCUS.)

THE Hibiscus is an ornamental genus of the Mallow family, of which a hardy shrubby species (*H. syriacus*), is known in some districts as the Rose of Sharon, and a tender shrubby one as the Rose of China (*H. Rosa-sinensis*). Most of the species are herbaceous, known as Rose Mallows, and may be found in gardens in this country. Late in summer the brackish marshes along American rivers are gay with the pink Hollyhock-shaped flowers of the Swamp Rose Mallow (*H. Moscheutos*) a species which does well in gardens, and is worthy of a place there. Farther south and west, there are several other species, all showy and desirable in large gardens; one of these (*H. grandiflorus*) has rose-coloured flowers with a deep red centre, which are sometimes a foot across. The most brilliant of all is the Scarlet Rose Mallow (*H. coccineus*), a strictly Southern species, which is found in marshes from the Carolinas, southward and westward. We (*American Agriculturist*) had long known this plant from herbarium specimens, and were glad to receive this spring some roots from Florida, which enabled us to see it growing. In its native localities this forms stems 4 to 8 feet high, but ours only reached the lesser height. It is very smooth throughout, and has large long-petioled leaves, which are parted quite to the base in five divisions; the flowers, which are abundantly produced from the axils of the upper leaves, are bright scarlet, and when growing wild are 6 or 8 inches across. Our plants produced flowers scarcely more than half that size, which is probably in part due to a severe drought which was experienced, and in part to the fact that the plant does not bloom until late, and the cool nights check its development. By the time it is well in flower, it will, no doubt, be cut down by the frost, but it is so showy a plant that it is worth growing even if it can be enjoyed but a short time.

Seed Saving and Packeting.—Having, yearly, a good many seeds to save and clean, my experience induces me to add to the directions given at page 412 on seed saving, what I find an important point, viz., that the name of the seed be written with ink on the paper box. Accidents will at times happen to loose labels or slips of paper, and pencil writing rubs. If the boxes are made of a large newspaper sheet (folded so that the white margin suits for writing the name on), they will last several seasons, and a slight difference in the sizes will permit of a number going one within another, each lot being turned over on its face, thus excluding dust and industrious spiders. Often with us the same seed is put into the ready marked box of the previous season. Such small particulars save that invaluable commodity, time, not to speak of eyesight and memory. Where seeds of several colours of one plant are being saved, no eye can distinguish all the different varieties; therefore, efficient naming on the box, and at once, is imperative.—F. J. HOPE, *Wardie Lodge, Edinburgh*.

Sedum carneum variegatum.—This is a useful Sedum, well adapted for indoor decoration. It grows freely, and may either be cultivated in pots or in suspended baskets. I saw a great quantity of it the other day in baskets in the conservatory at Floors Castle. Its long variegated shoots, from 3 to 4 feet in length, hung in profusion over the sides of the baskets, and with excellent effect. In small pots it is very suitable for ornamenting the fronts of shelves,

over which it droops gracefully. It is constantly in decorative condition; the leaves are small, oblongish, and of a delicate brown and white colour. Like other Sedums it may be readily increased by means of the small side shoots, or, indeed, by a small piece from any part of the plant. A light, somewhat open, soil suits it best.—J. MUIR.

Cassia corymbosa.—This fine old plant does not appear to be so much known as it deserves to be. For training on pillars or on back walls of plant-houses or conservatories it is most useful. It commences to bloom in June, and continues in flower to the end of the year. If cuttings of it are struck in spring and grown on they will be found to be very serviceable for autumn decoration. In the flower garden this Cassia is a gem; blooming, as it does, till frost cuts it down. Some plants of it put into the open borders in June commenced to bloom in July, and only ceased when frost cut them down on the 4th of this month. The day before I might have cut three or four dozen blooms from one plant. I may add that it will bear 4° or 5° of frost without injury, and I would recommend those who have mixed borders or large beds to give it a trial.—J. C., *Tyenham*.

The Scarlet Barberry.—I have been much pleased with the remarks of "J. S. W." (see p. 481) on this subject; I have often admired this Barberry in the woods and flower gardens at Drumlanrig. Early in spring it is one mass of beautiful sweet-scented flowers, which soon become mingled and lost amongst pale green leaves; and, in autumn, the bright scarlet berries adorn the drooping shoots long after the autumnal tints of the foliage have passed away. Why is such an ornamental plant as this not more extensively planted in our public parks? If I recollect rightly, it is but scantily, if at all, used in any of our great London parks, and certainly I have seen it in no others. It is a plant, however, well worth a place either in public or private grounds.—J. MUIR.

Fertilising Aucubas.—Your correspondent "W. N." (p. 525) states, that the male and female organs almost always attain their perfect development at the same time, when both organs are found in the same flower. Now, although flowers in which the sexes are thus simultaneously developed are by no means invariably self-fertilised, the phenomena of dichogamy, heteracemy, or successive development of the sexes are tolerably general among plants morphologically hermaphrodite. Of course, in these cases self-fertilisation is as impossible as in monocious or dioecious flowers. These forms are classified as protogynous or protandrous, according

as the female or the male organs are first developed. Examples of the first are *Potentilla anserina*, *Plantago lanceolata*, and *Luzula campestris*—of the latter, *Campanula*, *Pelargonium*, *Malva sylvestris*, *Parnassia*, and nearly the whole of the important orders, *Caryophyllaceæ* and *Compositæ*. Simultaneous development cannot, therefore, be said to be "almost always the case."—G. S. BOULGER, *8, Westbury Road, Harrow Road*.

Removal of Climbing Roses.—Is it possible to move old climbing Roses without destroying them? If so, which is the best way—i.e., is it better to try to move as much of the roots as possible, or ought they to be cut? Also ought the Rose bushes themselves to be cut down, and, if so, how low?—Q. [The removal of climbing Roses that have been standing a long time in one place is difficult, and not often successful, young plants often becoming effective before the old ones have recovered. If attempted, let the removal be done in the first week in November. All good roots should be left, removing only the bruised portions, but taking away all upward-tending suckers. Stake securely after planting, that the wind may not loosen and move the plants, and cut away all unripe wood; leave all the rest until spring; then cut away the dead wood.]

The Scarlet Rose Mallow (*Hibiscus coccineus*).

THE FRUIT GARDEN.

THE GRAPE VINE.

Propagation and Planting.

THE presence of such a scourge in this country as the *Phylloxera vastatrix*, with which it is almost hopeless to contend when once it has established itself in a Vinery, makes it more important than formerly that every Grape grower should raise his own Vines. Were this practice generally adopted, the spread of the disease would doubtless be greatly checked. In those places where it has broken out most destructively, it has pretty clearly been traced to the nursery, or other establishment, from which the Vines have been obtained. Considering, therefore, how great the risk is, and how easily and cheaply the Vine may be propagated at home, I would recommend the practice of planting young Vines from eyes the first year, wherever possible. I have seldom adopted any other plan, and I have always found such plants make just as good cane as one-year old plants, which would probably cost 10s. 6d. each at the nursery. There are two methods of raising plants from eyes. Hitherto the usual plan has been to insert the eyes in small pots filled with soil, from which they are afterwards shifted into larger pots as the plants grow, and eventually planted out in the border. The other, and better plan, is to strike the eyes on small turves, which are afterwards transferred to pots or the border when the plants have grown a little. By this plan the Vine may be said to be planted as soon as the eye is put in, for from that time it receives no check whatever, which is the whole secret of the matter; and any healthy Vine eye so planted ought to make a vigorous cane the first year, unless prevented by accident. During the last ten years I have propagated hundreds of Vines in this way for potting and planting, without failure in any instance. Besides, a hundred Vines may be raised just as easily as a dozen, and as many supernumeraries as can be accommodated may be planted for fruiting the first year; whereas, had such to be bought they would cost a considerable sum of money. When the plants are struck and grown on in pots till the planting stage, they receive a check every time they are shifted, let the operation be ever so carefully performed; this arrests the growth at a very critical period; and the chances are that failures will be the result, so far as getting a good cane the first year is concerned. Besides, pot plants often and unavoidably suffer from neglect in watering, which has a stunting effect upon them, leading to premature ripening at the neck, from which they do not recover the same year. An uninterrupted growth from the beginning is the secret of raising young Vines from eyes; and this is secured most certainly and easily by the turf system.

Propagating.

The *modus operandi* is very simple. I first of all secure shoots for eyes from the best ripened Vines, always preferring short-jointed lateral shoots to leading ones. These are generally taken off in November or December, when the Vines are pruned, labelled, and laid in soil by the heels in a cool-house till wanted in spring, taking care they do not get parched for want of water at any time. During the interval a small quantity of light, tough, fibry turf, free from wire-worm, is procured and stored in a heap in order to kill the Grass roots before using it, as these grow and are troublesome when the turf is used fresh; otherwise they do no harm. When the time arrives for planting the eyes in February, or early in March, the best turf is selected, and cut into pieces 6 or 7 inches square and 2 inches deep, a hole large enough to bury a small Walnut in the centre of each piece being scooped out at the same time. The sods are then arranged closely together in a square, on a temporary platform of boards, or on the floor, where they can receive a bottom-heat of 70° or 75°, and where the atmospheric temperature ranges from 65° by night to 80° by day, with plenty of light and sufficient ventilation when required. At this stage, also, if any danger is apprehended from wire-worm, I give the sods a good soaking with boiling water, which generally settles such vermin and kills the weeds as well. I then prepare the eyes, by cutting them out with a scateur, half an inch above and below the

bud, and taking a slice off behind each with a sharp knife nearly into the pith. A single eye is then planted in each turf, and covered over slightly with finely-sifted light soil; the crevices between the turves are also filled up, and covered over on the top with just sufficient soil to hide them; then leave an even surface for watering, and the operation is finished. I may here state that I have started Vine eyes in a considerably lower temperature than is here recommended; but, like cuttings generally, they require a rather high temperature to start them successfully at first, as the vitality is apt to flag, and the buds to perish, under a temperature that would be quite sufficient to bring the buds into leaf were they still upon the Vine. I, therefore, recommend the above temperature as safe and quite high enough. The only attention the eyes will require after planting in the sods will be occasional watering. A sprinkling with tepid water is generally enough, for the sods retain their moisture for a long time. When the eyes break, and have made a few fully-developed leaves, the turves should be examined; and if the roots are found to be pushing out at the sides, they must be re-arranged more thinly—say 18 inches or 2 feet apart each way, and the intervening spaces filled up as before, with fine soil, to the depth of the turves. The night temperature should also be raised at the same time to 68° or 70°, and the day temperature should range by day from 75° to 85°, according to the weather. At this stage it will also be seen which plants are likely to be the most vigorous; and if more eyes have been planted at first than are required, the weakest may be discarded to save space, and only a few more than will be wanted, retained in case of accidents. From this time the plants will grow rapidly, and the young rootlets will soon be ramifying in all directions in the fine soil which surrounds the turves; and the advantages of such a rooting medium will be discovered when the Vines come to be planted in the border.

Planting.

If all has gone well, the plants will require to be transferred to the border four or five weeks after they have been re-arranged, as, by that time, the roots will be encroaching upon each other. Presuming the inside border has been prepared, the position of each Vine should be marked off, and the site smoothed with an iron rake. The permanent Vines should be planted along the front of the Vinery, 5 feet apart, to allow of two rods to each Vine eventually; and between them should be planted supernumeraries, for fruiting the following year, or longer if required. This will leave the plants 2½ feet asunder. In addition to these, another row, consisting of supernumeraries entirely, should be planted along the middle of the border 2½ feet apart, so that they will just catch the wires where the front supernumeraries are stopped, as will hereafter be directed. In this way nearly the entire roof is covered with bearing wood the first year, and a heavy crop of Grapes is secured the year after planting, without interfering with the permanent Vines. I am here supposing the Vinery planted to be a "lean-to," but a span-roof would be planted in the same manner, only double the number of Vines would be required. Should a dull day not happen opportunely for planting, it should be done in the evening after the house is shut up. The soil about the plants should be allowed to get dry a day or two before, in order that the turves with the roots hanging to them may lift without injury, and when all is ready each sod should be lifted with the hand, and the roots pulled away steadily from the light soil, which, being dry and shallow, will offer no obstruction; and all the roots will come away easily without the loss of a spongicle. Presuming the plants have been prepared near the house where they are required it is better to carry them in the hand, as they are lifted, to the place where they are to be planted; and as one man deposits each turf on the border in its place, another covers the roots over with a little soil. After all are planted they should be watered with tepid water, and each Vine must be supported with a small stake until it reaches the wires. In this way I have planted some scores of Vines in half an hour, and so little was the check they experienced, that I have never had to shade the plants afterwards; whereas, had the plants been transferred from pots, and had the roots to be disentangled and spread out, shading and nursing for some time afterwards would have been indispensable. In recommending the above plan of raising and planting young

Vines, it is, of course, presumed that an inside border has been prepared for them, if only a strip sufficient to allow of planting inside the house. When the border is all outside, and the Vines have to be brought through holes in the front wall, one-year-old plants are to be preferred for planting. When I have had to operate with these, I have generally raised the Vines the year previous by the turf system, transferring the turves to 12-inch pots after the eyes were struck, and growing them on without bottom-heat, and well exposed to the light during the summer, and planting them the following spring. Those who cannot raise their own Vines must, of course, buy them from the nursery or elsewhere, and they should see that they are free from disease, true to name, and well ripened, by selecting their own plants at some respectable nursery. Nearly all nurserymen sell Vines, but all do not grow their own stock, but contract with private growers or others to grow the plants for them; and, as it is merely a commercial speculation, the plants are as often as otherwise grown in bottom-heat, or under the shade of other trees, and turned out in autumn, in a partially ripened condition, to the nurseryman, who places them out of doors, exposed to all weathers, till the leaves fall off, or until he can find accommodation for them under glass. The effects of this treatment upon ill-ripened Vines with soft tender roots are simply disastrous, and such plants are unfit for any purpose, though thousands are sold every year for fruiting and planting. If the intending planter will, however, buy his own Vines from the raiser in autumn, and winter them himself in a cool house, he is not likely to be victimised. Some prefer planting when the canes are ripe in autumn, just before the leaves are shed, in order that the plants may get partially established and be ready for a start in spring; but the advantages in this respect are hardly appreciable, and as autumn planting necessitates the making up of the border before winter sets in, the soil gets soddened, and the fibre of the turf decayed long before growth commences. It is, therefore, better to defer planting till March. The canes should be cut down to within about 2 or 3 feet of the pot six weeks before planting. This length of cane will be required to reach the bottom wire to which the cane is tied after it is planted. When the border is ready, and the soil has subsided, which it always does in newly-formed borders, a semi-circular hole about 3 feet wide and 6 inches deep must be taken out opposite each of the holes in the front wall, through which the Vines are to be taken. The Vines should then be shaken thoroughly out of the pot, and the roots carefully combed out with the hand. The point of the cane is then pushed through the hole in the wall, and while one person inside ties it securely to the wire, another spreads the roots out with a radius on the bottom of the hole, covers them with soil, and waters them. No part of the cane should be buried, as is often done, in the erroneous belief that extra roots are formed, whereas nothing of the kind takes place, as I have proved conclusively over and over again. True, roots will be emitted from the part buried, but it will only be at the expense of the natural and proper roots of the Vine. I have often taken up Vines so planted in the border, and in pots, at the end of the first season, to be certain on the point, and have invariably found that while the cane had struck afresh at the buried part, the natural roots had scarcely moved at all, but remained almost in the same condition in which they were planted, whereas those that were not buried made the best roots, started into growth soonest, and made the strongest canes. After the Vines are planted, the border where the roots are, and for a few feet farther out, should be covered with 15 inches of litter and leaves, which will afford a gentle heat to the roots, and greatly promote success.

(To be continued.)

TESTING GRAPES.

THE remarks of Mr. Ingram on this subject are highly interesting. Descriptions of this kind cannot fail to be instructive, especially to those who may be contemplating the introduction of any of the varieties into their Vineries; few people care to plant out any kind of Vine extensively which they have remotely heard of by name only. When explicit and elaborate observations on their various

characters and peculiarities are publicly pointed out, then the selecting of sorts to suit the requirements of all is no difficult matter, even with those who had been previously ignorant about Vines. With this end in view I would like to supplement Mr. Ingram's paper with some notes of mine which I have derived from tasting the fruits at many different places and daily seeing the Vines growing for many years. These include both new and old; and, probably, I cannot begin with a more fitting object than the old and useful

Black Hamburgh, which, for all ends and purposes, never fails. If it does not keep so late as some other sorts, it is better adapted for early forcing, and may be had in that way before any other. It is generally grown to come in about midsummer, and used from then until autumn; but it will keep to the new year, and early ones have been obtained at that time. As an amateur's Grape it stands pre-eminent; it is easily managed at all times; it will either grow in a hothouse or in a cool greenhouse; it can always be depended on for fruiting from one to a hundred years old, and it is as well adapted for pot culture as otherwise. Like all varieties, there is a possibility of overcropping it, when imperfections in some form or other follow; otherwise, it may be said to enjoy immunity from the various debilities to which most varieties are subject. It is a Vine which no one will ever make a mistake in planting, either by itself or with any other variety with which I am acquainted.

Duke of Buccleuch.—This is the nearest approach to the last mentioned that has yet been produced. Where the Hamburgh succeeds this will not fail. They are so alike in their requirements and adaptations that the remarks on the former are equally applicable to this. It is three weeks or a month earlier than the Hamburgh, and the berries are double the size. It sets and swells very freely, and the fruit keeps long after it is ripe. It grows very freely, forming strong canes in one season and bearing a superb crop of fruit the next. It is a variety which has justly been awarded a considerable amount of patronage since its introduction; but it is not yet so extensively planted as its merits deserve.

Gros Colman.—In size of berry this fine looking fruit is nearly as large as the Duke. It is a free grower, free setter and swells well. It must not be over-cropped or grown in too cool a temperature, or it does not colour well. It is of Continental origin, and one of the finest Grapes which has ever been imported into this country. It can easily be had ripe in June, and will give succession and remain in perfection until the following February. Like other good Grapes there are plenty who do not entertain any high opinion of it. This is entirely for want of knowledge of its good qualities. There is nothing peculiar or unmanageable about it that need deter anyone from planting it as a late black Grape, according to the space they have at command.

Trebbiano.—This, when thoroughly ripened, is a very excellent late light coloured Grape. I tasted it this autumn at Drumlanrig, and it had a flavour as high and rich as Muscat of Alexandria. It grows freely in any kind of Vinery, and keeps until the Vine shows leaf in the spring. It is not a variety which I would recommend to be planted in quantities; but, as a useful late Grape, it is highly worthy of a place in every Vinery.

Duchess of Buccleuch.—This is a favourite Grape of mine. In character it is like the Hamburgh; it is second to none in flavour; the bunches are very long, generally from 1½ to 2 feet, nicely shouldered and tapering to the point. The berries are small, but, when fully cropped, the whole has an extremely handsome appearance. It should never be omitted from the list of an early house, for it will fruit more certainly there, and perfect as heavy a crop as any other variety. It also does remarkably well for fruiting in a pot.

Gros Guillaume.—This is often grown under the name of Barbarossa; and Scacliffe Black is said to be synonymous with both, which I very much doubt. The bunches of this kind are generally very large and handsomely proportioned. It requires a Muscat-house temperature to ensure success, though in favourable localities it does perfectly in a Hamburgh one. The flavour is somewhat like that of the Hamburgh, but not quite so sweet. The fruit hangs for months after being ripe; the berries are quite round, and of medium size. It grows freely, but, in some cases, does not produce bunches in such abundance as might be desired. The foliage becomes prettily tinted in autumn.

Royal Muscadine.—This is a useful early sort, and is well adapted for forcing. It is not often grown in quantities, but as a variety in the early house it is always acceptable. The bunches are generally small, as well as the berries, which become transparent when ripe. The flavour is good, and it bears a very heavy crop either when planted out or in a pot.

White and Grizzly Frontignan.—These are alike in their characters and may be grown together. They are both exquisite in flavour, with small bunches and berries. The Grizzly is not of a

very pleasing or matured-looking colour when ripe, but this should be no obstacle when the flavour is so fine. Neither of them are very robust growers, but they thrive and succeed very well in a Hamburgh-house, and for early pot-culture they are always valuable.

White Lady Downes.—This is similar in every respect to the black variety, only different in colour. It will keep until April. It has no tendency to scald when swelling, as the black one does generally; but if it had, it would not be so much the fault of the Vine as the management to which it was subjected. No scalding need ever take place amongst Lady Downes, or any other kind, if plenty of air is admitted, and the house is kept quite cool during the whole period they are liable to be affected.

Buckland Sweetwater.—This somewhat resembles a white Hamburgh in flavour and character. It is a very useful kind for early forcing, and chiefly grown for this purpose. The bunches often attain a weight of 4 lbs.

Foster's White Seedling is another fine early white Grape, very pleasing in flavour, and deserving of general cultivation where Grapes are grown to be eaten shortly after they are ripe. It is nearly as large in bunch and berry as the last-named, and better flavoured. It grows freely at all times, and makes an excellent pot Grape.

These are varieties which have all been rigidly tested in every way for years, and not a flaw or blemish exists in one of them, so that each or all of them may be planted together with every certainty of their succeeding perfectly. I have purposely omitted mentioning any sort about which I have the slightest doubt, as certain kinds will only succeed under particular treatment of their own, and then often only partly. Those in Mr. Ingram's notes which I have best reason to feel pleased with, and which may safely be added to the above enumeration, are—Mrs. Pince, Lady Downes, Muscat of Alexandria, Black Alicante, Raisin de Calabre, Mr. Bass, Mrs. Pearson, and Golden Queen. The latter two I consider very worthy additions to our late Grapes, and they will fill a place in that way which at present can scarcely be considered to be occupied. J. MUIR.

Gros Colman Grape.—Those who assert that this fine Grape is only pleasing to look at should taste it in the condition in which it is now at Drumlairig. Even experienced judges would unhesitatingly pronounce it to be equal to a richly-flavoured Hamburgh ripened in July. What pleased me not a little was the mellowness of the skin, which melts away in the mouth, leaving no vestige behind. No other late black Grape is so much liked at Drumlairig as this, and certainly, for exquisite flavour, none other need be desired. Gros Colman is but an indifferent Grape when indifferently grown, but cultivated as it is at Drumlairig, it has no equal as a black Grape, not even among kinds considered first-class summer varieties. —J. M., *Cherford*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Venn's Black Muscat Grape.—We have received from Mr. Dodds, Gladstone Villa, Bishopston, berries of this excellent new black Grape, to which the Royal Horticultural Society lately awarded a first-class certificate. It produces large well-shouldered bunches, the berries of which are oval, covered with a delicate bloom, firm and juicy, and rich in Muscat flavour. It is said to be equal to the Black Hamburgh in hardiness, and free-bearing; and to ripen about ten days later than that variety in a house without artificial heat. This year it was ripe by the middle of August.

Pears on Apple Stocks.—It is very rarely that Pears succeed well on Apple stocks. Sometimes they will give much promise for a year or two, and then fail. The Winkfield and Summer Bon Chrétien will often grow freely for a few years. We have raised about one peck of fine Seckel Pears on a small tree grafted on an Apple five years old, but the union being imperfect, it broke off at the surface of the ground. We cannot recommend the practice, except to those who are fond of unsuccessful experiments, not one in a hundred succeeding after the first year.

Ne Plus Meuris Pear.—For five long anxious years have I waited for this Pear to become eatable, and this season, although matured quite two months before its usual time of ripening, it is now (Dec. 7th) simply delicious in flavour, but rather gritty at the core. With the exception of Passe Colmar, Ne Plus Meuris ranks among the best Pears of the season. I wish I could induce your readers to furnish us with short notes on the ripening of Pears this season in different parts of the country, and also to give us some account of the varieties best suited to their particular locality. In this way much valuable information would be diffused in a small compass.—R. GILBERT, *Burghley, Stamford*.

A Good Pear Orchard.—The *Rochester Rural Home* quotes a local paper for an account of the 3-acre Pear orchard in Genesee County. It was planted with Duchesse d'Angoulême trees ten years ago, the whole cost of culture being about £220. The seventh year it began to bear, and yielded 20 barrels, at £2, or £40. The eighth year 180 barrels were gathered, and sold at £1 4s. per barrel, or for £216. The ninth year, 220 barrels, at £1 per barrel, brought £220. This year, 204 barrels, at £1 2s. brought £224 8s. Whole receipts, £700 8s., less £220 cost, leaves a net profit of £480 8s., the Potato crop among the rows more than paying for cultivation. This is one of the successful orchards; many more, from bad selection, neglect, &c., do not yield one-tenth part of this sum.

VALUE OF PINUS PINASTER FOR SEA-SIDE PLANTING IN THE WEST OF SCOTLAND.

IN THE GARDEN of the 25th of April and 9th of May of the present year I had occasion to recommend this tree as invaluable for shelter in sea-side planting. That it is a handsome tree, when well grown, may be seen from the accompanying representation taken from a careful drawing of a specimen of it which grows within a mile of the sea at Monreith, the property of Sir William Maxwell. It is about eighty years old, and measures 61 feet in height, 9 feet 8 inches in girth at 2 feet from the ground, above the swell of the roots, and 8 feet 10 inches at 4 feet from the ground. It is said not to succeed on heavy soil; here, on a light soil, all that seems essential to its growth is that it should not be crowded, but that air and light should be freely admitted to it. In this it appears to differ from most other Pines, and to a want of success, resulting from an opposite course of treatment, may be attributed its want of favour with most planters as a forest tree. I should feel obliged to anyone who has tried the timber of the Pinaster if he would communicate his experience, either here or on the Continent in regard to it. The timber of this Pine has never been sufficiently grown in this country to be much in the market, although the price at the nurseries of young plants of it is low. Our experience is, that it will make timber on exposed coasts where other trees will barely exist. A broad belt, composed entirely of Pinaster, would form a grand and useful feature on a windward coast.

SALMONICEPS.

ORIGIN OF THE PHYLLOXERA.

MR. LICHTENSTEIN tells us he has seen the Phylloxera of the Vine fly off in swarms to the Garrigues and light upon the Kermes Oaks. We have no reason to doubt his word, but Mr. Balbiani, an entomologist, asserts that the Phylloxera alluded to is not that of the Vine; he does not in his letter (read at the Academy of Sciences, September 21st last) describe the differential characters of the two insects; but, supposing they do differ a little in colour, size, or aspect, all this goes no further than to prove that the Phylloxera found on Oaks differs a little from that found on Vines, and it does not prove in the least that the Phylloxera of the Oak cannot feed on the Vine and *vice versa*, or, that having so totally changed its food, it may not thereby assume some slight modification of aspect and appearance. He says, the Phylloxera of the Vine is found under three different forms, males, females, and certain abnormal states. Now, might not these abnormal ones be either in a state of transition, or strangers from some other habitat? It is very easy to say Phylloxera comes from the west and cholera morbus from the east; but trace them as far west or as far east as you please, and you will never find a country where either the one or the other exists permanently in the swarming multitudes constituting an epidemic; there, as here and everywhere, they exist permanently only in a latent state—a state of germ or ova according to some—a state of another species or variety, capable of being modified into that particular one, according to my views of them; and in either of these states (whichever the true one may be) requiring a particular medium to attract and foster them so as to cause a real epidemic. That this is necessary, appears from the very interesting experiments made by M. Delorme in 1872, before the President and members of the Society of Agriculture of Vaucluse, which consisted in infecting perfectly healthy Vines with the radicles of others swarming with Phylloxera, not one of which had become acclimatised up to August last, the Vines remaining perfectly healthy as before. We know the medium required for the incubation of the ferment causing cholera morbus, or, as I think, for the fostering of the modifications in those ferments causing less deadly forms of cholera, which are permanently among us, diarrhoea, dysentery, cholera, sporadic cholera, &c. Give them plenty of bad drains and cesspools, filthy dwellings, and foul water, and the species is modified, and the epidemic breaks out. I say we know the medium cholera morbus requires, but we do not know the one Phylloxera requires; and Vine-growers should seek it out, for as long as the medium remains the exciting cause, it is in vain to hope for a cure. This medium might possibly be a weakened state of the Vine brought on by pruning during successive ages; or it might be the sequel of oidium. The prolonged controversies between the adherents to, and the opponents of, spontaneous generation have necessitated a vast amount of microscopic observations and crucial experiments; these, if they have had no other result, have made known a whole world of beings, vegetable and animal, hitherto never dreamed of, and have decisively proved that given mediums produce particular

LARGE PINUS PINASTER AT MONREITH, IN THE WEST OF SCOTLAND.

kinds of animalculæ; but whether the germs of every species of them exist permanently around us, or whether one species may be modified into another, still is and probably will long remain a matter undecided. It is well known in France that you may plant bushels of Truffles, and not one will ever increase in size or beget a second tuber. But if you plant the acorn taken from an Oak which has had Truffles at its foot, you will in three years (in the proper soil, of course) see Truffles begin to appear where never one was seen before. Now, where do these come from? The same people who prohibit the importation of French Vines into Italy, to keep out Phylloxera, and tell you that Phylloxera comes from America and cholera from Asia, will probably answer without hesitation, "Why your Truffles have come from Périgord!" What, inside of an Acorn? Easier said than proved.

Versailles.

F. P.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

THERE is a considerable amount of ambiguity connected with the term "Amateur" as regards gardening. Under this designation some include all engaged in the pursuit who do not make a business of it, ranging from those who have an extensive establishment down to such as cultivate a small plot of ground, with it, may be, a plant house or Vinery upon it—for pleasure or profit, or both combined. These latter are what may be looked upon as amateur gardeners in a legitimate sense of the term; they are a class which may be met with in all parts of the kingdom, but more especially in the suburbs of large towns, and they are continually increasing. Numbers there are who occupy their leisure hours in attending to the different kinds of flowers, fruits, and vegetables, which they endeavour to cultivate, often under difficulties; and for the assistance of such we intend, henceforth, to publish weekly directions, not simply as to the time when such and such operations should be carried out, but in order also to convey, as far as possible, an idea how to perform the work in a way best calculated to produce satisfactory results. Vegetable life in the open air may appear almost dormant during the short sunless days of winter, yet, in a garden, every day and week in the year brings with it some duty to be performed, the omission of which will tell its own tale through the coming season by an absence or deficiency in the particular department neglected. If there is one pursuit more than another, wherein the guiding rule ought to be, "Never defer until to-morrow that which can seasonably be done to-day," it is gardening; and where the amateur's gardening operations are thus carried out, the fuller will be his measure of success. In the vegetable department immediate attention should be paid to the removal—if not already done—of the remains of all summer crops, such as Peas, Beans, Cauliflower, and Cabbage stumps; these latter should be placed in the bottom of any ground that is being trenched, where they will slowly rot and materially assist the roots of any vegetables afterwards grown upon the space so treated. The cropping of all vegetable ground should be so arranged that a third or a fourth of the whole space can be deep-trenched every year; and, unless the sub-soil is naturally bad, an inch or two, or even more in good land, of the bottom-soil should be brought to the surface each time the ground is trenched. This is of the most service in old gardens, where shallow cultivation has been practised, and the effects of incorporating a portion of the under-soil with that on the surface, which has become, by length of culture, almost effete, will be found of more service than even a heavy dressing of manure, without the trenching. Where there exists a deep surface-soil, or the sub-soil is composed of clay, I should advise the application of a good dressing of manure at the time of trenching; but, when the sub-soil is of an open, gravelly, or sandy character, the manure should not be applied until the ground is about to be cropped, owing to the wasteful influence of heavy rains carrying the manural elements away. The old system of ridging up vacant vegetable ground is right in moderately light soils, but, in such as are very retentive, it has this drawback, especially where it has to be cropped early, that the ridges throw off the water into the alleys, which, consequently, get much above their share, and when the ground is levelled for cropping, the wet hollows do not for some time get dry enough to admit of early-sown seeds progressing freely. In strong heavy soil there is nothing equal to draining efficiently in the first instance (without this the results can never be satisfactory), and, as early in the autumn as the ground is at liberty, digging it over deeply without ridging, leaving it as rough on the surface and open as it can be, so that the rains can pass freely through it. The pruning of Apples and Pears should, if possible, be completed before the close of the year; in cold weather it is never a pleasant job, and in the new year the cold is usually more penetrating than before Christmas. In small or moderate-sized gardens large Apple or standard Pears are out of

place, doing much injury to other things that are grown near them; yet, in an orchard—their proper place—the quantity of fruit they yield individually is greatly in excess of even a number of small trees, however well managed. Moderate-sized bush-shaped Apples and pyramid Pears on Quince stocks are both useful and ornamental on the margins of the walks in any garden; and, so grown, are productive in soils fairly suited to the growth of these fruits. Pears on the Quince stock are naturally more disposed to form large quantities of fruit buds than to make much wood; consequently, they do not require so free a use of the knife. Apples, on the other hand, grafted on ordinary stocks, and grown in a kitchen garden in well-manured ground in which their roots feed along with the vegetables for which it was intended, are generally disposed to make too much wood and an insufficiency of fruit buds, a condition aggravated by hard pruning of the shoots. The only method of correcting this over luxuriance and inducing a fruitful habit is to root-prune, an operation best done early in autumn. In the case of trees in the condition just described, and often bearing little or no fruit, the first or second week in September is the best time to root-prune. Thus treated, they are often induced to set a large quantity of fruit buds the same autumn. It is not yet too late to perform the work, but it should not be attempted to the extent that vigorous unfruitful trees require to be operated upon, after the middle of January, or there is danger of, for a time, injuring the trees. The operation is in itself simple; in the case of a bushy tree, say 8 or 10 feet high, open a trench 15 inches wide, on opposite sides, at 3 feet from the stem, not going more than half way round the tree at one pruning, but sufficiently deep to meet with all the roots that extend in a horizontal direction; cut them clean off with a knife; do not leave them jagged with the spade; and if the tree is very vigorous, tunnel under it at, say, 2½ feet deep, to see if it has any strong roots that strike straight down. If such should exist, cut them clean off at the above depth from the surface, and then fill in all the soil, making it firm as it is replaced. Even in the case of very vigorous trees that have hitherto shown no inclination to bear, this will generally check them sufficiently; if, however, in a couple of years' time they are still over strong, the roots may be similarly cut on the sides not yet operated upon. Trees trained upon trellises, that are over vigorous, should be similarly root-pruned. In branch-pruning such trees as are under consideration, it is a bad plan to leave the shoots too much crowded, for several reasons: the fruit does not receive sufficient sun and air, and in windy weather the branches lash each other so as to knock much of it off. Trees that bear freely and are as large as is desirable, may each year have their current seasons' growth cut right out, confining them to the size which they have already attained; but if they do not bear much, and are at all inclined to make over-strong wood, they can only be kept to a limited size and induced to fruit freely by having recourse either to root-pruning or to lifting operations, both of which tend to diminish over-luxuriant growth, and to throw the trees into a fruitful condition, which, when secured, will probably last for many years.

Herbaceous Borders.—These should be gone over before severe frost sets in, removing all decayed tops; but everything at all tender must be mulched with a few inches of dry material, such as old tan, half-rotten leaves, dry shaly dung, or, in a locality where it can be procured, small pieces of Gorse, stuck round each plant, are an excellent protection from frost. There are few finer objects in a garden than well grown examples of Pampas Grass, and although, by some, it receives the character of being sufficiently hardy to stand our severest winters, such is not the case, except in the most favoured localities; consequently, it is better to give it protection. This can be done by tying the head close up like a broom, doubling the points down so as not to leave the plant too high; put a wheelbarrow load of old tan or leaves round the collar of each plant, then take some good long Wheat-straw and place it in the form of thatch all round; get four stout sticks and insert them in the ground close in with the straw, then run some twine round the whole, drawing it up tightly, and tapering it off to a narrow top. The sticks will hold both twine and straw in their place. If the operation is done neatly, plants so treated have not an unsightly appearance, and will bear, without injury, the severest frost.

Greenhouse.—This, in an amateur's garden, is generally devoted to a little of everything, a circumstance which necessitates a compromise of treatment in the different things grown therein. Camellias will now be coming into flower and must receive enough water at the roots, for if the atmosphere is too dry they are almost certain to throw off their flower-buds; but with the continuous use of water for the general stock of plants there is not much danger of over-dryness. Such plants as Pelargoniums, Primulas, and Mignonette in pots, should be placed in the best position as to light, this applies to all plants that grow through the winter; anything like

Azaleas, that are quite dormant will, whilst in such state, bear a worse position. See that nothing remains in cold pits or frames, that cannot be effectually covered in case of severe frost.

GARDENING FOR THE WEEK.

Indoor Plant Department.

Conservatories.—When the earliest *Chrysanthemums* become unsightly they should be removed, and their places filled by such as have been treated with a view to their later flowering. These must be carefully managed so as to prolong their blooming period as much as possible; they should have a little heat at night so as to allow of some air being admitted at the bottom with top ventilation to allow the moisture to escape. *Camellias* are plants which may be induced to flower at any time of the year, yet they do not like too much forcing, for when hurried too much the buds are almost certain to drop off, especially if the atmosphere is too dry. The proper time to regulate their season of flowering is when they make their growth and set their buds; by inducing a portion of the plants to make early growth, and by keeping others later, a longer season of flower will be secured. Consequently, if it happens that the bulk of these plants is flowering too much together, and not so early as may be required, the best plan is to at once remove part of the plants to where they can receive a little heat, and have a sufficiently moist atmosphere to accelerate their flowering, and also induce an earlier growth and disposition to come into flower earlier in future seasons. This separation of the stock is especially necessary where a considerable number of the plants are planted out, and consequently cannot be removed to regulate their time of flowering; where such is the case it is better to reserve those that are planted out for whatever time there is the greatest demand for the flowers, and to use the plants that are in pots for earlier work. That general favourite, *Daphne indica*, will now be opening its flowers and tempting us to cut more of them than we should do, as there is no plant with which we are acquainted that is more injured by cutting than this. No matter how vigorous and strong the plants may be, not more than half the current season's flowers should be cut, and these with as small a bit of the wood attached to them as possible. Winter-flowering *Epacris* will now be coming into bloom; most of these possess a somewhat stiff upright habit of growth; individually this may be considered a disadvantage, but in the conservatory, intermixed with numbers of other plants of bushy or pendent growth, they are of great use. *Epiphyllums*, now in great beauty, should be placed in prominent situations, and elevated so as to stand clear of their neighbours. *Agaves*, *Dasyliirions*, *Yuccas*, *Cordylines*, and *Rhopals* might with advantage be much more extensively used in conservatory decoration than they are. Most of the species of these genera harmonise well with all kinds of blooming plants, and with little change in the materials at command they can be so altered from time to time as to avoid that objectionable monotony of each plant being always in the same position. Keep a good look-out as to the requirements of the next three months as regards blooming plants. During that time forcing pits will be taxed to the utmost in forwarding the different plants required for keeping up the supply. Introduce regularly in succession such plants as *Hyacinths*, *Narcissus*, *Lily of the Valley*, *Tulips*, *Crocuses*, *Solomon's Seal*, and *Spiraea* (*Hotelia*) *japonica*, all of which will be required in due course. Do not start more of these, however, at any one time, than are absolutely wanted, and never subject them to too much heat, especially top-heat; see, moreover, that their root-action is in advance of their growth above ground, or disappointment will follow, in the shape of a paucity of flowers. Keep them also as near the glass as possible, so as to prevent a weak unsatisfactory growth; for in the case of plants required for conservatory decoration, where of necessity they are subject to a much lower temperature than that in which they have been brought into flower, it is essential that every means should be taken to render them capable of remaining in bloom for as long a period as possible. Assist them with weak manure-water as they progress; yet, before applying this, see that there is abundant root action, otherwise it will do more harm than good. Give all the light possible to the first lot of *Cinerarias* and *Primulas*, now coming into flower, by keeping them near the glass. Apply liquid manure every other time they are watered, the object being to get the growth as strong and sturdy as possible; for when introduced to their quarters in the conservatory they are generally far from the glass, and more or less under the shade of larger plants, where they quickly become unsightly, unless they are in good robust health at the time of their introduction; with this view give air on all favorable occasions. Syringe *Azaleas* coming on for early flowering once in the day, to induce them to push

kindly, and to keep down insects; but let it be done sufficiently early to admit of the foliage getting quite dry before night, otherwise this will cause these plants, for providing cut flowers, to be deficient in substance. We often hear it said that this or that flower will flag as soon as cut, when, in many cases, if the plants had been treated so as to give the blooms the requisite substance, there would have been no reason for complaint. The temperature of the water applied to all plants that are being forced should always be a few degrees warmer than that of the house in which the plants are placed; and where they are in bottom-heat, the water should be as warm as the plunging material, and, if this is deficient in heat, a few degrees warmer. At the same time we do not advocate the application of bottom-heat, only so far as to induce root action somewhat in advance of the growth above-ground; and in the case of plants that are intended for removal to the conservatory, or for producing cut flowers, we should always advise their being gradually withdrawn from bottom-heat after their roots had got sufficiently into action. A few *Genistas* and *Acacias* may now be placed in heat; of the latter, *A. Drummondii* and the old *A. armata* are the best for forcing. Introduce now a few more of the early spring-struck *Hydrangeas*. *Calla* (*Richardia*) *æthiopica* is a general favourite, and at no time is it more useful than during the winter months. Where it can be had in sufficient numbers a portion should now be placed in heat; these will quickly throw up flowers, when they are amongst the most telling of conservatory plants. Supply them plentifully with water. Do not keep the temperature of conservatories higher than is absolutely necessary to keep up a slight circulation in the atmosphere, as such would only shorten the duration of the flowers of many of its present occupants; and, until there is a considerable introduction from the forcing pit, it is not required high; 45° night temperature will now be sufficient.

Stoves.—Such things as winter-flowering *Begonias*, *Apelandras*, *Gesneras*, *Poinsettias*, *Euphorbias*, &c., should be placed at the coolest end of the house, and should receive all the light possible; with a little air whenever the weather will permit; but not in such quantities as to chill the plants, for that is unnecessary, and is, moreover, a waste of fuel. Do not keep too much moisture in the atmosphere, and keep the deciduous portion of the hard-wooded stock comparatively dry, yet not so much so, as to destroy the roots. Now, when the greater portion of the stock is at rest, persevere in the destruction of insects, the increase of which is now at a minimum. Every hour at this season employed at this work is re-paid ten-fold by the saving of time further in the spring, when every day brings its full amount of work. The night temperature should now be from 60° to 64°, allowing an increase of from 5° to 8° by day.

The Flower Garden and Pleasure Grounds.

Except in cases where alterations and improvements are in progress, routine work in this department will simply consist in occasionally refreshing the surface of beds and borders containing spring flowers and bulbs, and in keeping Grass and gravel walks in good order. While the weather continues open and mild the planting of shrubs and trees may still be proceeded with; but such work should now be brought to a close as soon as possible, or deferred until spring. In the meantime, however, plans may be matured as to the arrangement and selection of the trees and shrubs about to be transplanted. Due consideration should always be given to the selecting of species which will best harmonise with the architectural character of the building or buildings with which they are to be associated, as well as with their other surroundings; and the season of the year at which it is desirable to produce certain effects should also be considered. By the judicious employment of trees whose leaves attain a warm tint of colour as they decay, associated with Conifers and other evergreen trees and shrubs, an exceedingly pleasing effect can frequently be produced in the vicinity of country residences and elsewhere, at a season when such effects are most desirable and most likely to be appreciated. Deciduous trees and shrubs suited to this purpose, may consist of such species as the *Acer* or *Maple* of various kinds, and white or silver-barked *Birch*, which produces a remarkable effect among dark foliaged evergreens of various sorts. The *Populus fastigiata*, or Lombardy Poplar, may also be occasionally used in suitable positions, as may also *Scarlet Oaks*, the *Veutiau Sumach*, or *Rhus Cotinus*, and, in appropriate situations, drooping plants, like the *Weeping Cherry* and *Weeping Willows* (*Salix babylonica* and *S. caprea pendula*), with such varieties of the *Lime tree* or *Linden*, as *Tilia rubra*, *T. alba pendula*, &c., while the bright red wood of the common *Dog-wood* (*Cornus sanguinea*), may be so placed as to produce a very desirable effect, which may be heightened during the autumnal months, by clothing the naked stems of deciduous trees with *Virginian Creeper*. All newly-planted Conifers, or other trees

of which there may be any doubts as to hardness, must be accommodated with some slight protection during the first winter, should intense frost set in; and when the weather is moderately mild deciduous trees and shrubs, may, if necessary, be pruned now, while, the pruning of evergreens should be deferred until spring.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Indoor Fruit Department.

Vines.—If there be any foliage still remaining on Vines where fruit is still hanging it may all be removed at once; clear the whole out, and do not let any of the leaves remain lying about the floor or pathway, as they will serve no good purpose there. Grapes will suffer very little from damp or decay of any sort after this time. November 1 take to be the most trying month of the whole year for Grape keeping; this may probably be accounted for by the active state of the sap in its descent. All other things being carefully attended to, the fruit will not suffer so much for the next three months as it has done in the past one; do not give any more fire-heat than is absolutely required; it is not by inducing a high temperature now and then, but by a uniform temperature throughout, that preservation is ensured. As the weather is now very cold, a considerable amount of fire-heat will be required to keep up the desired temperature in those Vineries which have started into growth. As strong firing is resorted to, reduce the aridity of the atmosphere by sprinkling the surface of the border, paths, &c., place evaporating troughs on the flow-pipes, and keep them constantly filled with water. This is a very beneficial way of supplying moisture, but no water must be poured directly on the pipes to fill the house with steam, as many young and tender leaves and shoots are frequently scalded in this careless way; air must be given to these with still more care than formerly, and various modes have been devised for accomplishing this in the most advantageous manner possible. The best, and most simple, and efficient, that I have had any experience of, or seen tried, is that ingeniously invented by Mr. William Thomson. This consists in having the front flow-pipes incased in a thin outer one; the latter is perforated on the top, and is connected with the exterior by a projecting pipe through the front, where the cold outer air enters, mingles with the warmed air while passing around the incased hot-water pipe, and enters into the house through the small holes at a very genial heat. All the pipes need not be fitted in this way; two lengths are generally sufficient for a moderate-sized Vinery. Many of your readers will remember the very neat model of the system which the inventor showed at the great exhibition in 1851, and it has been adopted in many places with much success.

Pines.—Where last week's directions for these have been carried out the early batch of Queens will now be neatly and snugly started. The atmosphere about these should be kept very moist. Sprinkle the path with water hourly if necessary; never let the evaporating pans become empty. Stuff the space, which generally exists between the pipes and the walls with Moss, and keep the latter constantly moist by damping it with a pan; this keeps the atmosphere continually in a good growing state, and the harder the firing is the more freely is the moisture given off. Where no bottom-heat valves are placed to modify the temperature in that direction, the heat in the plunging material may become excessive, when the pots should be slightly eased, that a small space may be made between them and the fermenting stuff; this simple action lets the heat escape and prevents the tender roots from getting burned. Cover small pits in which suckers, &c., are placed during cold frosty nights, and see that the covering is removed throughout the entire day to admit all the beneficial light possible.—J. MITCH.

Hardy Fruit.

Where to plant fruit trees is a subject which was pretty fully adverted to by me some two years ago. On that occasion I advised all vacant walls of cottages, farm buildings, workshops, factories, warehouses, public institutions, the roofs of cottages, sheds, &c., to be impressed into the service of fruit production. A few attempts seem to have been made here and there to carry out this advice, but the major portion of our unoccupied walls and valuable roofs continue bald, unproductive, and unprofitable, as they were. Enough, however, has been accomplished to show the practicability and profitableness of planting unfurnished walls. Many a cottager pays his rent with the Golden Apricots that furnish and adorn the gable end of his cottage. It matters little what the seasons are; these trees enjoy a charmed life. The heat from the chimney and the overhanging eaves do it all, and provide the tree, rich in bloom, with a panoply of safety. Peaches and Nectarines, of the choicest varieties, would do equally well, and might bring more money. Against the north and east walls would grow first-rate Golden Drop or Jefferson's Plums, and Morello and other Cherries. There is never any difficulty in commanding good prices for such fruits.

Figs and Grape Vines would thrive well on the roofs of stables, cow-houses, cart-sheds, &c. The heat of the animals would prove of great service in moderating the severity of the cold, and would put such trees through their danger-period safely. Numbers of exhausted trees, of second and third-rate varieties, cumber the ground to little purpose up and down the garden. These should be uprooted, and an equivalent space set apart, if possible, to the most approved sorts, on the best stocks, and in the most profitable form, as bushes, pyramids, cordons, dwarfs, and standards. Further, the hedge-rows in many of the inside fields of farms and meadows might be planted with standard Apples, Pears, Plums, Cherries, Damsons, Walnuts, Quinces, Medlars, &c. This would adorn the landscape with cheerful beauty and fill the national fruit basket to repletion. In many places in woods or on their outskirts, sheltered by the density of their masses, groups of our hardier fruits would thrive, and form so many lights to the frequently excessive shade of large masses of timber trees. The corners of Grass meadows or dairy farms might often be planted for the double purpose of fruit and shade. Such hints will, it is hoped, prove suggestive to many readers, and set them to plant fruit trees in all waste places at once.—D. T. FISH.

Kitchen Garden.

Remove all decaying leaves from Cauliflower and Lettuce plants in frames; scatter dry charcoal dust or wood ashes freely amongst them, give abundance of air, even on frosty days, if the sun shines, and see that all the glass is clean so as to admit a maximum amount of light during the short days. Frames and lights that will shortly come into use for forcing should be thoroughly cleaned, to be in readiness when required for use; have a good supply of dry Fern straw or other protecting material at hand for covering anything that may require it if severe frost sets in. Lettuces may be successfully grown in pots in an unbeated orchard-house; and, although it involves rather more labour than merely planting them in the borders of the house, there is an advantage in being able to move them at any time; the borders, too, at this season are often too hard and dry for promoting rapid growth in any green crop. If there be any difficulty about a supply of well-blanching Endive, it may be easily pushed forward by taking a few plants at a time into the Mushroom-house. Where there are plenty of roots there will be no difficulty in having a good supply of forced Asparagus now. The hot-beds from which the first lot is taken may be used for sowing Carrots and Radishes; or, if a lining can be put round to renew the heat, a second lot of Asparagus roots may be placed in, or the frame may be planted with early Potatoes. Pot a few roots of Sorrel and push it forward in heat for flavouring. Successions of Balm, Borage, Tarragon, Mint, Tansy, &c., should also have attention. If mice are troublesome to recently sown Peas or Beans; scatter sifted ashes thinly all over the drills, this will preserve them from their attacks. Soot may be used freely to stop the depredations of sparrows and slugs. Get all vacant plots of land manured and trenched, or dug without delay, when the weather is suitable for such work. I believe when the manure is in a condition to go on the land (provided the ground is vacant), the sooner it is taken there and dug in the better. Exceptions to this rule are often made in the case of poor hungry sands or gravels, on the plea that the rains will wash it down beyond the reach of the roots if applied to the land before the crop is put in. The true and obvious remedy in such a case, however, would be a good dressing of clay or marl; I believe this is the best way to improve land that is so sterile that it cannot retain what is put on it. The most fertile land is also, as a rule, the most absorbent and retentive; and, in fact, its fertility is, in some measure, due to its absorbent and retentive qualities. To improve the staple of light land and make it more retentive, heavy dressings of clay should be put on at this season, clay or clayey marls, or marls in which chalk abounds; whichever is most accessible may be applied to light land with very considerable advantage. In fact, this should be the first means adopted for its improvement. From fifty to eighty, or even one hundred, loads per acre may be applied, according to its condition. It should be run on during frosty weather, be spread over the surface, and remain exposed to the action of the weather till just before the land is required for cropping, when it should be lightly forked in. Salt is another substance that may be beneficially applied to light land, or any land where the crops suffer from drought. Salt is largely used on the light lands of Norfolk, and its effect is, in a dry season, little short of marvellous. It is best applied in early spring as a top-dressing, at the rate of from 10 to 15 lbs. per rod. Whenever a garden is overrun with slugs or snails, salt is an excellent thing to use. When mixed with soot, it forms an excellent dressing for poor lawns that soon scorch with the sun heat in summer; but it is best applied in showery weather in spring.—E. HOBDAY.

THE ARBORETUM.

TRANSPLANTING PINES AND EVERGREEN SHRUBS.

I AM compelled, reluctantly, to offer a few strictures upon the somewhat lengthy article which you have published on this subject at p. 503. Its author being personally unknown to me, I trust that he will receive my remarks as they are intended, viz., to place a few facts, which cannot be controverted, in juxtaposition with what I doubt not he believes to be good practice, but which, in reality is not. The writer of the article in question winds up his remarks as follows:—"Having thus considered the subject of transplanting in general, the season and circumstances best suited for the various species, and the many precautionary measures to be observed in the process, and having also glanced at the methods usually employed in removing large specimens, and the sizes most to be recommended for the purpose, it would be improper, before concluding, to omit mentioning the immense success in this department of landscape gardening achieved by the late Sir Henry Seton Stewart, of Allanton (the Evelyn of his day), with the aid of the machinery devised by himself, of which the implements used now-a-days are but slight modifications and improvements." How can this be, when I assert, without fear of successful contradiction, that in February, 1831, more than forty-four years ago, Sir Henry Stewart's machine and implements were found useless for the removal of three Cedars of Lebanon, varying from 28 to 33 feet in height, with trunks from 3 to 4 feet in circumference; and in November of the same year for the removal of another tree 43 feet in height, 48 feet diameter of branches, and 6 feet in circumference of trunk—and that a machine and implements equal to the task had to be invented by me? The four trees then moved at Elvaston Castle are in high vigour now, and since then have nearly doubled their dimensions. During the last forty-four years, with machines of my own invention, of which there are six sizes, I have removed great numbers of large trees. The trees to which I allude varied from 1 to upwards of 21 tons; not one of these has been operated upon with machinery at all like Sir Henry Stewart's, and all of them, except four, have been removed without any previous preparation and without regard to the season of the year. The late Mr. William McNab, curator of the Royal Botanic Gardens, Edinburgh, under whom I studied three years, honoured

me with several visits at Elvaston, whilst I was engaged in laying out the gardens and grounds there; and, on one occasion, happening to come just as a tree was being taken into the grounds, he expressed himself much gratified with the novelty and excellence of the means used in the operation of transplantation. Of the first four large trees moved in February, 1831, the first three were prepared in August, 1830, by order of Lord Harrington; they were all Cedars of Lebanon. About a fortnight after I had commenced operations in laying out and enlarging his

grounds, he took me to see them, and then asked me if I knew anything about the removal of large trees; I told him I was conversant with Mr. McNab's system, and he then enquired whether I knew anything of Sir Henry Stewart's. I told him I did. Lord Harrington then requested me to have the trees at once prepared upon Sir Henry Stewart's system. Next day I had all the three trees prepared by cutting a circular trench, 2 feet wide, down to the sub-soil and quite below all the roots, at a sufficient distance from the trunk, in proportion to the respective sizes of the trees, as to ensure success; all the earth taken out of the trenches being thrown away, I had them filled with suitable soil to encourage the growth of roots for the next two years, prior to removal, as directed by Sir Henry Stewart. About a fortnight after this his Lordship astonished me by saying that he should remove these Cedars during the following February. I asked what good was to be expected from this preparation by that time, for I knew that Sir Henry based his success on the trees being prepared for removal two or three years beforehand in order that they might form root-lets the first season and roots the second. And as I was expected to remove the Cedars almost at once, I was obliged to say plainly that were Sir Henry Stewart there in person with all his appliances he could not remove one of them, nor would he attempt it. His practice, I added, had been

confined to comparatively small, deciduous trees, with both flexible branches and roots. He denudes all the roots up to the trunks, and then brings his "two-wheeled janker," and divides the roots as well as he can, and then lashes the pole of the janker to the stem of the tree; that being done, the tree is pulled down and carried horizontally, root first. I explained that to follow this plan with the Cedars at Elvaston, with their extremely brittle roots and branches, would render them fit only for the faggot pile, if the effort were successful to carry them at all; but even that would have been impossible, as the janker would be put out of sight by branches extending

Barron's Tree Transplanters.

from 15 to 20 feet from the trunk. His lordship seemed much disconcerted, and I saw he was disappointed; but I adhered to what I had said—that it was impossible, upon Sir H. Stewart's system, to remove the trees so as to make them grow, but I told him if he would risk his trees, and accord me his support, I thought I could remove them successfully, and, having left the matter in my hands, these trees were removed in February. In November following, when forming terraces and laying out what was afterwards called Mon Plaisir, I was obliged either to cut down, or remove a Cedar, in front of the castle, 33 feet in height, 48 feet across the branches, and 6 feet round the trunk. I preferred trying the latter course, and was again successful. These four trees were all removed as my first attempt, and then measured, and have increased in girth and height as follows:

INCREASE IN GIRTH AND HEIGHT MADE FROM THE TIME WHEN THE TREES WERE PLANTED TO THE PRESENT, VIZ., FORTY-THREE YEARS:

Height in				Circumference in			
1831.	1874.	Increase.		1831.	1874.	Increase.	
ft.	ft. in.	ft.	in.	ft.	ft. in.	ft.	in.
No. 1 ... 28 ...	77 10 ...	49	10	No. 1 ... 4 ...	7 2 ...	3	2
No. 2 ... 32 ...	81 8 ...	49	8	No. 2 ... 3 ...	9 8 ...	6	8
No. 3 ... 35 ...	76 1 ...	41	1	No. 3 ... 3 ...	9 6 ...	6	6
No. 4 ... 33 ...	54 10 ...	25	10	No. 4 ... 6 ...	9 9 ...	3	3

DIENSIONS AFTER REMOVAL IN FEBRUARY, 1852:

Height.				Circumference.			
ft.	ft. in.	ft.	in.	ft.	ft. in.	ft.	in.
No. 1 ... 46 0	6	1	No. 3 ... 58 6	6	0
No. 2 ... 55 6	6	3	No. 4 ... 44 9	7	10

It may be asked why Nos. 1 and 4 did not increase in the same ratio as Nos. 2 and 3; but the cause is easily explained, viz.:—No. 1 was planted on the south side of the grand avenue, and shaded from the solar action by very tall trees; Nos. 2 and 3 were planted on the north side of the same avenue, which runs east and west; consequently, they were at all times exposed to the sun's rays, and No. 4, after it had been planted only a few years (in consequence of surrounding objects), had its branches foreshortened several feet, thus lessening its elaborating powers. The accompanying woodcut, made from a photograph, represents a large Scotch Fir removed in July, and brought upon one of our machines eight miles into the show yard at Leicester the week before the show which was held in 1868; the week after it was removed five miles and planted, and still lives, after having been eleven days upon the machine, exposed to a cloudless sky and a broiling sun every day during the whole of the time. This tree was seen by the thousands of visitors who attended the Royal Agricultural and Horticultural Society's shows, when they met conjointly at Leicester, some six years ago.

WILLIAM BARRON.

Barrowash, near Derby.

PACKING TREES FOR LONG JOURNEYS.

Drying and exposure to the air always injures roots. The longer the exposure, and the greater the drying process, the greater, of course, is the injury. Digging up trees when destitute of leaves, and leaving them an hour or two in the shade, produce but little or no harm; but to remain in the sun, or to expose them for a whole day to the air, should not be allowed. If they cannot be set out or packed immediately, they should have the roots plunged in a bed of mud to give the surface a thin coating, or the roots should be immediately buried in mellow soil or sand until further operations are commenced upon them. Nothing is more common than serious injury to trees by deficient packing. Nearly all those from nurseries are carried to some distance. Some are taken by waggons; and the practice has not been an unusual one to leave the roots exposed for days together. Many trees are now sent by steamboat and railroad, and are sometimes weeks on the way. In such cases, the complete protection and preservation of the roots is a matter of the greatest consequence. The packing in which the roots are imbedded, should as nearly as possible, resemble in effect the bed of moist soil from which they are removed. This is most effectually accomplished by first dipping the roots into mud, and then surrounding them with damp Moss. At the same time, to prevent external injury, the roots and branches must be well surrounded with straw if in bundles, or with a strong box if the latter is used. To pack well requires considerable practice and skill. It also involves some expense, which purchasers often begrudge, and hence, to save 5 per cent. in this way, they often lose 20 per cent. of their trees by exposure. The great number of trees packed annually, and the large amount on which the work is imper-

fectly performed, induces us to offer a few practical hints to beginners. In the first place the materials must be provided. For packing bundles these must be, 1, a prepared bed of mud, which is best made by setting half a hogshead (made by sawing in two) in the ground, in which to stir thoroughly the soil and water; 2, Moss; 3, straw, of which Rye is much the best; 4, straps of stout leather, 2½ inches wide, with very strong buckles at one end; 5, cord, about one-fourth or one-third of an inch in diameter; 6, strong sewing twine; 7, a strong packing needle, 6 inches long; 8, bast-mats, sacking, or gunny-cloth; 9, direction labels.

To pack a bundle, first lay down on the ground two of the leathern straps, already spoken of, about 3 or 4 feet apart and parallel with each other; on these deposit a layer of long, straight, Rye straw, about 2 or 3 inches in thickness. If the trees are long, lay down another strap, and another length of straw lapping on the last. Then place a layer of Moss on one end of the straw, and the roots of the trees, previously dipped in the mud, on the Moss. Proceed to lay on the trees successively, sprinkling Moss among the roots, and straw among the stems and branches, taking care, at the same time, that the roots lie as compactly as possible with each other, and the stems perfectly parallel and not crossing. When a sufficient number of trees are made into a pile for a bundle, a layer of Moss is laid over the roots, and straw on the stems and branches, as below. The straps are then brought up, and two or three men draw them strongly through the buckles, until the whole is compressed into a round and compact bundle. Next, in order to secure the straw firmly to its place (having previously, while drawing the bundle together, adjusted it evenly over the whole surface), a cord must be passed round it from bottom to top at intervals of 6 inches to a foot, first tying it

Fig. 1.

to a strong root, and then proceeding upwards by successive loops as in fig. 1. To keep the straw to its place, these loops must be tightened with great force, which is best accomplished by two men working together, one of whom forms the loop and keeps it to its place, and the other passing the cord round a short strong stick, draws upon it by this means with his whole strength, the first one holding it to its place while another loop is made. The end of the bundle being slightly raised on a bench from the ground, the work is rapidly accomplished—the leathern straps being successively taken off as the cording proceeds. Lastly, a mat or piece of sacking is spread under the roots, after they have been well covered on every side with Moss and a coating of straw, and its corners are drawn together, and the whole well secured by sewing with twine. The direction label is then sewed or corded on, and the bundle is ready for shipment (fig. 2). This is the simplest mode of packing a bundle, and answers well for all of moderate size. Usually, however, there are some modifications or additions needed. If, for instance, there are several sorts of trees and several of a variety in the bundle, as usually happens in filling retail orders, it is best to tie up each variety by itself, with a small straw band, and with an admixture of straw among the stems. These are then all placed together on the straps, Moss mingled well with the roots, and brought compactly into a bundle, and kept together by a few twisted straw bands. The external coating of straw and cording is applied afterwards. Very large bundles are likewise more securely packed by first binding them together, as above mentioned, and strapping them externally afterwards. Ropes, doubled, so as to form a loop, are sometimes used instead of a strap to draw the bundles together, but they are more apt to cut or bruise the trees than the flat surface of the leather, and need a thick bed of straw under them. Others employ a windlass for tightening; but this should be used with caution, and with a full supply of straw interspersed among the stems. In the spring of the year, when the buds start and the bark consequently is free, great care should be used to prevent bruising, by a copious use of straw—and all easily broken trees, such as Plums, dwarf Pears, &c., need special care of this kind. Fifty trees of common size, 7 or 8 feet high, will be enough for an ordinary bundle, covered with a mat or sack 3 by 5 feet—and two active men will pack, in the best manner, about six or eight in a day. Boxing Trees should be adopted where they are sent very long distances. For trees in large quantities, it is most economical to employ large boxes, such as will hold 200 or 300 7-foot trees. The size may be about 9 or 10 feet in length, and over 2 feet square inside. These, when filled, will weigh about 700 lb. They should be of boards not more than three-fourths of an inch thick, with battens or cleats across the ends and middle, secured by wrought nails, and when the box is filled, they should be banded with hoop-iron at the ends. In filling, the trees

Fig. 2.

should be secured to their places occasionally by cross pieces placed within, and nailed at the ends from the outside. These prevent the boxes spreading, keep the tops and bottoms from being crowded off, and hold the trees firmly to their places. The same care as for bundles is needed in mudding the roots, packing in Moss; and securing the stems from bruising by an intermixture of straw. A lever, like that for filling flour barrels, may be carefully used for compressing the contents. For marking boxes, a mixture of lamp-black and turpentine is most convenient, as it immediately sinks into the wood and becomes dry at once.—*Rural Affairs*.

METHOD OF CLIMBING TREES.

PEOPLE who live in wooded districts frequently find it convenient to have some way of readily climbing a tree. In felling trees where timber is valuable, much damage and waste is prevented by being

Fig. 1.—Climbing Trees with Stirrups.

able to bring the tree down exactly where it is wanted. To do this it is often necessary to climb the tree to be felled, and, sometimes, an adjoining one. In making surveys in wooded districts, or in taking a more extended view in places that are partially wooded, it also becomes necessary to ascend a tree. The *Agriculturist* describes a ready method of accomplishing this by means of a pair of spiked stirrups as in fig. 2. This contrivance is a flat iron bar, about an inch wide and a quarter of an inch thick, bent to pass under the boot in front of the heel, with loops by which it may be strapped to the leg. A sharp, stout spur is fixed at the lower part, and, when the stirrup is worn, this spur comes at the inside of the foot. When a person wishes to climb a tree, one of the spikes is thrust into the bark and the other, a step upward being taken each time. A cord is carried around the waist, and, if it be necessary to do any work while up the tree, the climber can pass the cord around his body and the tree, and make himself secure. The rope also answers to draw up tools or anything else that may be wanted. The method of climbing, by aid of these stirrups, is shown in fig. 1. [The natives of the Pacific islands have a very simple method of climbing the bare, lofty shafts of the Cocoa-nut tree by fastening round their ankles a thick skein of flax or Cocoa-nut fibre, of sufficient length to keep the feet some 18 inches apart. The tree is then encircled with both arms, and the fibre of the material round the ankles binding against its rugose bark, a sufficient hold is given to enable the climber to shift his grasp higher up, and thus rapidly reach the summit without much exertion.]

Fig. 2.

THE LIBRARY.

ECONOMIC GEOLOGY.*

WORKS on geology, from the rudimentary treatise for beginners to the higher and more elaborate standard volumes of Murchison and Lyell, are numerous. These, however, deal for the most part either with the science, *per se*, or, less frequently, in its relation to agriculture, building-stone, or coal and metallic ores. Until this volume appeared, no author had undertaken to point out the position of geology in regard to the arts and manufactures, and a want very much felt has thus been ably supplied. But, "whilst primarily intended for the student of applied geology," to quote the words of the preface, "it may be useful to the agriculturist, builder, miner, civil engineer, manufacturing chemist, and others who have to deal with minerals; and, at the same time, may not be devoid of interest to the general reader." In fact, the author has managed to condense within very portable limits, and submits in a most readable volume which is embellished with excellent cuts, a mass of information respecting the mineral and metallic substances used in the arts and manufactures, which could only be otherwise obtained by repeated reference to a variety of independent sources, and this alone must render the work a most useful text-book to a very large section of the community. Besides this, we have a large number of the earlier pages of the book devoted to the consideration of various kinds of soils, and their geological origin, with many most useful remarks upon drainage and mineral manures. Reviewing these pages more especially from our own point of view, we extract a portion useful to all cultivators.

Soils and Sub-soils.

The soils upon which the agriculturist has to operate are usually classified as sandy, sandy or light loams, loams, clayey loams, heavy or retentive clays, marls, calcareous loams, peaty soils, or bog-earths. This classification has reference chiefly to composition and texture, a special chemical composition (silicious, calcareous, &c.) being necessary for the profitable growth of particular crops, and a certain mechanical texture (friable, porous, &c.) suiting best for the permeation of rain and air, and the descent or spreading of special roots and rootlets. Loams, consisting of fertile admixtures of sand, clay and humus or decayed vegetable matter, may be regarded as typical soils, which become, on the one hand, light, by a preponderance of sand, and on the other, heavy, by a preponderance of clay. But whatever their composition and texture, these soils geologically speaking, are mainly of two sorts—soils of disintegration, arising from the waste and decay of the immediately underlying rocks, together with a certain admixture of vegetable and animal *débris*; and soils of transport, whose ingredients have been brought from a distance and have no geological connection with the rocks upon which they rest. Under the former are comprehended such as arise from the disintegration of limestones, chalks, traps, granites, and the like, and which are directly influenced in their composition, texture, and drainage, by the nature of the subjacent rocks from which they are derived. Under the latter are embraced all drift and alluvial materials, such as sand, shingly *débris*, miscellaneous silt and clay, which have been worn from other rocks by meteoric agencies, and transported to their existing position by winds, water, or ancient glacial agencies. Besides these there are also soils of organic origin, such as peat earths, and vegetable mould or humus, which is to a great extent also of animal origin or elaboration. Indeed, in all superficial soils there is a certain amount of vegetable and animal matter—the decay of plants, the droppings of animals, the exuvia of insects, the casts of the earth-worm, and the like, conferring upon them that dark friable and loamy character so indicative of richness and fertility. Beyond the soils proper, which come immediately under the plough, there are in most situations a set of sub-soils, differing from the true soils, and which cannot be ignored by the farmer. Thus peat may lie upon clay, sand upon clay, common humus on sandy clay, and clay may rest upon shingly *débris*; while in many of our alluvial flats (old lake-sites and estuaries) there may be several alternations of peaty matter, clay, sand, silt, and marl, before the underlying rock-formation is arrived at. In general, the sub-soils differ notably in colour and consistence from the soils above them. The true soils are usually of a darker colour, from the larger admixture of humus, while the sub-soils are lighter in hue—yellow, red, or bluish, from the greater preponderance of iron oxides. The soils are also more or less friable in their texture, while the sub-soils are tougher, more compact, and more

* "Economic Geology." By David Page, F.G.S. Blackwood and Sons.

largely commingled with rubbly and stony *débris*. The soils are usually little more than a mere surface covering, while the sub-soils may be many feet, or even yards, in thickness. All these soils and sub-soils repose on the rocks below, but it is only where they are immediately derived from these rocks, by disintegration, that they are materially influenced by this relation. Hence, for agricultural purposes, it is necessary to have two sets of geological maps—one showing the range and disposition of the older rocks, and another exhibiting the disposition of the superficial accumulations by which these are masked. On examining two such maps of any district in Britain, it will be seen that the soils of disintegration occupy limited areas in comparison with those of transport. In all our river-valleys, dales, levels, fens, straths, and carse, the soils are those of transport, and consist of miscellaneous river-drifts, the alluvia of former lakes and sea-beds, or of the sands, shingles, and bouldery clays of the glacial epoch. Over the higher uplands—largely over carboniferous districts, and on many of the other formations—the drifts of the glacial period are thickly spread, so that it is chiefly on the hilly portions of the chalk, the oolite, the mountain-limestone, the old slates and schists, the traps and granites, that we find soils of disintegration. And even there, there are many patches of bouldery clay, sand, and shingly drift, whose materials have been brought from other and distant localities.

Soils of Disintegration.

All rock-surfaces, however hard and refractory, break up, in course of time, under the influence of meteoric agencies. Those containing lime are acted upon by the carbonic acid of the atmosphere; those containing iron by the oxygen; and all suffer more or less through frosts, rains, winds, and other kindred forces. These disintegrating agencies are further aided by the root-growth of plants, by the burrowing of worms and other earth-dwelling creatures, and in no small degree by the acids (humic, geic and crenic) generated by organic decay. From the hardest granites, basalts, and lavas, to the softest chalks and marls, all are undergoing this disintegration; and the soils thereby produced will vary in depth, composition, and texture, according to the softness and mineral character of the rocks, and the length of time during which they have been subjected to the comminuting forces. If we take a geological map of the British Islands and turn to the districts coloured as granitic, we shall find them largely covered with a thin cold clayey soil derived from the decomposition of the subjacent granite. Ordinary granite is composed of quartz, some variety of felspar, and mica; and it is the felspar (silicates of alumina, with minor proportions of soda, potash, lime and iron) which mainly yield this poor moorland covering, the sterility of which is aggravated by its general high elevation, whitish colour, and the impervious nature of the rock on which it rests. We say whitish colour, for, area for area, white soils take in less heat than dark-coloured ones—the former reflecting and the latter absorbing the solar rays. If we turn, on the other hand, to the tracts coloured trappean, we will find them covered, for the most part, with a dark-coloured dry, crumbling soil, noted for its fertility and certainty of cropping. This arises from the disintegration of the softer trap-tuffs, amygdaloids, and wackes, and consists, according to the analysis of the late Professor Johnston, of silica, alumina, and lime with varying proportions of soda, potash, and iron; its fertility and mellowness being augmented by its colour, which absorbs the sun's heat, and by the fissured structure of the rocks beneath, which carries off all superfluous moisture. In slaty and schistose tracts—that is, those coloured metamorphic, cambrian, and silurian, we find that where these rocks are not masked by diluvial drifts, they have weathered into thin clayey soils of indifferent fertility, partly owing to their elevation, and partly to their retentive texture—green nutritive pastures occurring, as in the southern uplands of Scotland, only where the high inclination of the beds, with their slaty structure, affords a ready and efficient natural drainage. The soft, sandy, and marly strata of the new red sandstone break up into a dry fertile soil, especially suited for Barley and green crops; while the clayey and marly beds weather down to a stiff retentive clay, like that of Cheshire, much better adapted for permanent pasture than for the varied requirements of corn culture. Over the lias and oolite, consisting of alternations of calcareous and argillaceous strata, we have those noticeable belts of dry, rubbly, and stiff clayey soils, which characterise a large portion of England, from Yorkshire on the north-east to Dorset and Somerset on the south-west—the calcareous freestones forming the drier ridges, and the clays the moister valleys. In the south-east of England, the tracts coloured as Hastings sands, Weald clay, greensand, gault, chalk, and London clay, are respectively characterised by thin, light sandy, stiff clayey, or dry calcareous soils—the direct results of the disintegration of their immediately underlying rocks. Indeed, this connection between the

soils and subjacent rock-formation is best seen along the secondary and tertiary tracts of England—that is, from the new red sandstone upwards through the lias, oolite, wealden, chalk, and eocene deposits of the London and Hampshire basins. No doubt sporadic patches of diluvial drifts occur here and there to break the connection, but, generally speaking, the soils, modes of culture, crops (Wheat, Barley, Beans, Hops), coincide with and are favoured by the lithological belts, as depicted on the geological maps of the country. Nor do these lithological areas influence alone the white and green crops of the husbandman; they are equally, if not still more, operative in the growth and value of the timber trees of the forester. The Firs and Larches which thrive so magnificently on the decomposed mica-schists of the Scottish Highlands would be but poor stunted sticks on the thin cold clays of the granite; while the Oaks, and Elms, and orchard-growths which flourish on the marly clays of the new red sandstone, would become stunted and gnarled if transferred to the drier and scantier soils of the chalk and carboniferous limestone.

Soils of Transport.

When we turn to the soils of transport we find them of a much more miscellaneous character, and occupying much more extensive and unbroken areas. Some consist of river-drifts—shingly gravel, sand or alluvium; others of old lake sites—peaty earth, clays, sands; some of old estuary beds—tenacious clays and silts; others, again, of wind-blown sands and sand-dunes; and many of glacial drifts—sand, shingly gravels, and stiff bouldery clays. These may of themselves form the arable soils, or they may constitute the sub-soils, and be overlaid by a coating of less or greater thickness, partly derived from their own disintegration, augmented by the growth and decay of plants, and partly formed by the plough and repeated cultivation. But, whatever be their nature and origin, they are little, if at all, influenced by the subjacent rock-formations, and have to be studied and treated by themselves. Over the old red sandstone, the carboniferous and permian systems, which consist mainly of sandstones, shales, and clays, there is in most parts of the British Islands a thick coating of diluvial or bouldery clay, very stiff, retentive, and sterile. Much of this boulder-clay has been brought from a distance by ice-action; but the major portion, perhaps, is but the ground-up material of the formations on which it rests, hence its reddish tints on old red tracts, and its dark blue colour over the coal formation. In many of our larger plains—Strathmore and Strathearn, for example—there is a very miscellaneous assortment of drifts—sands, gravels, shingly *débris*, and boulder-clays; and in the lower and wetter portions, peat earths and alluvia, the remains of silted-up lakes, or of lakes still in process of obliteration. In our lower carse and valleys—Carse of Gowrie, Falkirk, and along the Humber—there are large expanses of soft plastic clay (old estuary bottoms) of great fertility, but of difficult and uncertain cultivation; while such tracts as the Fens of Lincoln, Romney Marsh, and the like, are chiefly marine silts and marsh growths. Sand-dunes, or link-lands along the sea-shores, and inland marshes, also occupy extensive tracts; and, indeed, by far the larger area of these islands consists of sub-soils and surface soils, having no connection with the rocks on which they rest, and little, if at all, influenced by their proximity. These soils of transport must therefore be studied and treated by themselves, whether as regards fertile and permanent admixture, draining or manuring. Along with these soils of transport may be classed some of organic accumulations, such as peat-moss and bog-earths, which have no geological connection with the sub-soils or rocks on which they repose. Such accumulations are often of great thickness, and rest on old estuary and lake silts, on sands, and on clays of totally different origin; and indeed, as in the case of Blair Drummond, the peaty stratum may be altogether removed in order to expose the finer and more fertile clay that lies below.

Fertile Admixture of Soils.

It must be obvious that soils varying so much in their origin, composition, and texture cannot be all alike cultivable and fertile, and hence to correct the one by admixture with the other, to render this one more friable and that more compact, to improve this one by drainage and that by manuring, is the sum and substance of judicious and successful farming. Taking a good loam (an admixture of clay, sand, and organic matter) as the type of productiveness, we find some soils too sandy and light, and others too clayey and heavy. Some soils, though active, soon become exhausted, and are apt to be parched in dry seasons; and clayey soils, though often rich and absorbent of ammonia from the atmosphere, are apt, in wet seasons, to become water-logged and unworkable. It is thus that some soils are too cohesive, others not cohesive enough; some deficient in one element, and others having that element in excess. It is the duty of the skilful agriculturist, therefore, to correct these deficiencies by

admixture, and to bring his soils as near as he can to the normal condition of easy cultivation and fertility. If we take an estate of some extent, for example, and after careful pitting and examination, map out its soils and sub-soils, and find that some of its fields consist of stiff retentive clay resting on the rabby outcrops of the strata below, others of thinnish loam resting on a sub-soil of sandy clay, some in the hollows and along the streams of soft peaty earth, and the remainder skirting the sea-shore of dry shelly sand, the question arises—How are we to effect a permanent improvement of these various soils by drainage and admixture? The cold retentive clays, on which insolation is spent in evaporating moisture before it can impart any warmth, may be dried by draining, and subsequently cut up and rendered friable by admixture with the shelly sand; and such clayey soils may also be improved by burning, which not only renders them freer, but converts their potash from an insoluble to a soluble state. The thinnish loam might be deepened by sub-soiling, provided there was nothing deleterious in the clayey sub-soil; the soft spongy peat-earths, which throw out their seeds and roots after frosts, might be improved, as every one knows, by an admixture of the clays; and the loose dry sands can be readily compacted and rendered fertile by a good addition of clay, as we have seen near the estuary of the Eden in Fife, where sands, almost useless as sheep-runs, have been converted into profitable grain-fields by admixture with the soft red brick-clays which abound in that locality. We have taken an imaginary instance; but, whatever the example, there are few estates which have not their fertile and unfertile portions, and all of which might be permanently improved by such admixture of soils, and these admixtures often lying within their own boundaries. We refer to lands at moderate elevation, and naturally fitted for the plough; for there are wide expanses in Britain which should never be broken up from their natural pasture, unless they could be put under glass—a provision which fluent expatriators on the conversion of waste lands forget to make allowance for in their Utopian speculations. For such admixtures as those to which we have referred, a geological knowledge of the district is indispensable; and be it observed that fertile admixture of soils is a permanent improvement—a creation, as it were, of new soils—and not like manuring, which is a mere temporary expedient, soon losing its effect, and requiring to be repeated at every rotation.

Draining.

The same may be said of draining, and there is much in draining that depends on the geology—superficial and lithological—of the district in which it is to be effected. The main object of draining is to get rid of superfluous water, thereby rendering the soil drier and more absorbent of the sun's heat, more friable and open in texture for the admission of air and rain, which prevent the generation of deleterious acids, more accessible to the tender permeating rootlets of the crop, and likewise more easy and certain of cultivation. Before excavating the drains, it is always worth enquiring whether the wet is retained in the surface soil by an impermeable underlying "pan," which, if broken up by the sub-soil plough, would be sufficient to let off the superfluous moisture through the underlying beds; or whether the thin clayey soil would not require all the moisture if it were cut up and deepened by sandy admixture? Again, in some very level tracts where sufficient fall is difficult to be obtained, it is also worth trying the nature of the subjacent beds to see whether they might be porous enough to receive and carry off the discharge of the drains. Under some morasses there have been found beds of open quartzose sand, which, when dug down to, were sufficient to carry off all the drainage water; and in the Wealden and chalk districts it is not unusual to find in the porous Kentish rag and chalk, which lie below, a sufficient outlet for the drainage of the superincumbent heavy clays and loams. This property of taking away surface water is possessed by all rocks having sufficient porosity, and especially by sands and gravels, chalks and limestones, absorbent sandstones and fissured trap-rocks. As draining, when thoroughly executed, should be viewed as a permanent improvement, every precaution should be taken to ascertain the nature of the soil and sub-soil to be operated upon, to fix upon proper depths so as at once to deepen the soil, and not to carry off the dissolved manures, to see whether there be surface stones on the estate for the filling of the drains, or whether these might be rendered more efficient by covering the tile-pipes by stones which have otherwise to be got rid of. The sole object of admixture and drainage is to render soils at once more easy of cultivation, and more certain and abundant in their productiveness. The qualifications of a productive soil are thus succinctly epitomised by Professor Ansted:—"It should be composed of nearly equal parts of three earths—sand, clay, and lime; it should contain a certain quantity of decomposing vegetable and animal matter; it should imbibe moisture, and give it back to the air without much difficulty; it should have depth sufficient to permit the roots of plants to sink and extend without coming to rock, to water, or to

some injurious earth; the sub-soil should be moderately porous, but not too much so: and, in case of need, the sub-soil should be able to improve the soil by admixture with it. The proper proportion of the various earths may vary from 50 to 70 per cent of silicious matter, 20 to 40 per cent. of clay, and 10 to 20 per cent. of calcareous matter. According as the climate is wet or dry, the soil should be friable or porous, or adhesive and retentive, and the best soil is that which, in long drought, is never very dry, and in the wettest seasons does not become choked and soured with water." To these remarks may be added those of M. Schübler (Jour. Roy. Agric. Soc.):—"The more an earth weighs, the greater also is its power of retaining heat; the darker its colour, and the smaller its power of containing water, the more quickly and strongly will it be heated by the sun's rays; the greater its power of containing water, the more has it in general the power also of absorbing moisture when in a dry, and oxygen when in a damp, state, from the atmosphere—and the slower it usually is to become dry, especially when endued with a high degree of consistency; lastly, the greater the power of containing water, and the greater the consistency of a soil, the colder and wetter, of course, will that soil be, as well as the stiffer to work either in a wet or dry state."

Belgian Horticulture.—We have received a copy of the "Annuaire de l'Horticulture Belge," for 1875, a book which has much to recommend it in the amount of useful information which it contains. Besides the calendar a good directory of the principal nurserymen, seedsmen, and landscape gardeners is given; in fact, of all connected in any way with horticulture in Belgium, together with a list of the principal horticultural societies, schools, and botanical gardens in that country. More than half the book is devoted to useful remarks upon horticulture, embodying a list of new plants and fruits, hints on pruning, Vine culture, &c., the whole being embellished by good wood-cuts.

MR. J. JAY SMITH ON CEMETERIES.

MR. J. JAY SMITH, of Philadelphia, who edited the *Horticulturist* after the unfortunate death of Mr. Downing, and who was the principal founder of the large and garden-like cemeteries that now occur near American cities, has lately made a horticultural tour in England, and sends us the following notes thereon:—"You suggest to me that my fourth visit to England should give me some right to say a few words on the present position of things in regard to planting, and you ask me to give my views on the topic of rural cemeteries. In the first place I would remark that I am surprised that evergreens are neglected in many quarters, and I would suggest that the Cedar of Lebanon, so adapted to your climate, should be more frequently planted. It is true that its growth is slow, and may take two or more generations to perfect; but what have you to show of such magnificence or of such historical value? There is nothing to equal it. I would say "Plant more Cedars—many more," and let posterity judge of your taste. I could add that my observation teaches me that those Cedars already planted are not always sufficiently cared for; many look dwindling, struggling for life, and it is of equal importance to feed trees as domestic animals. I have noticed many Cedars that want digging round, and pabulum supplied to their roots. This is so easily done that one wonders it is so entirely neglected. If we could have this magnificent tree in our northern latitudes in America, no money would be spared in nourishing it. A good Cedar transmitted to a grandchild would be a really valuable possession. And why are there no Cedars in the parks? The *Aucuba japonica*, so beautiful and valuable, has, I confess, become rather too common; but this plant (now fructified so as to bear fruit for the birds) is invaluable, and so is the Portugal Laurel, which is cut off by our northern winters in America, as it is occasionally even in Southern England; but prize these plants, for there is no substitute for them—no broad-leaved evergreen yet known to take their place. What shall I say of your English, and in fact European, mode of sepulture? You have not caught the idea which has been so popular in America; the human heart clings to the idea that families should be interred together, and while America provides ground in one paternal lot for parents and children and grandchildren, and more even in the future succession, the London cemetery provides only for the present family, and leaves children and grandchildren to provide for themselves. Is this Scriptural, and is it in accordance with those feelings implanted in us by God himself? It does not, accord with the American idea, nor, as we contend, with Nature's demands on our human sympathies. The love of kindred is

Annuaire de l'Horticulture Belge, par Fr. Burvenich, Ed. Pynaert, Ern. Rogiers, and H. T. Van Huile. Gand, Bureau de l'Annuaire.

implanted in our nature, and we yearn to rest with them at our decease. Dare I say that the English custom does not quite recognise this desire to rest together; may I add that the American custom fully does? Here we inaugurate cemeteries of such size that the remains of five generations may moulder together undisturbed. In England this mode of sepulture is impossible. The rural cemetery sells a lot of 6 or 7 feet by 3 feet, digs a vault and bricks it, that will contain three or six bodies only, and when successive claimants require space they must seek it elsewhere, probably at a distance from their beloved ancestry. Not so in our American plan; a son, say, buries his parents in sacred premises, where his allotment is so large that both he and his wife, and perhaps several generations to follow can all lie contiguously; he plants and adorns it and it is placed in the hands of trustees who follow each other in succession, and who are desirous of participating in the transaction, because they themselves inter their parents and their children there, and are deeply interested in the permanency of an institution deemed sacred to all the family. Sufficient time, it is true, has not elapsed in America to test the system thoroughly; but the feelings of the public on this subject are all for the maintenance of the charters governing cemeteries, and fortunately these institutions have originated, and are conducted by, gentlemen and men of taste. In England the separation is decreed of the coming from the past generation; in America all that can be done by human foresight is done to ensure a family resting place in perpetuity. What is wanted in England is sufficient appropriation of ground to grant family lots in which may be interred whole families in succession, planted in the most exquisite style of art with Cedars and evergreens especially, and I should be pleased to correspond with Englishmen desirous of benefiting their race in this respect. I deem the rural cemetery a need of the age. As for cremation, I dismiss it as not as yet adapted to the wants and feelings of survivors.

THE TREMELLAS.

THESE strangely curious Fungi are, for the most part, seen on old stumps or the dead branches of trees, whence they shoot forth their wrinkled and tremulous growths, which look more like a mere exudation from the stump itself than a veritable plant. The germs of reproduction are imbedded in the pulp, the sporophores being large, and the spicules usually elongated into threads. We find the Tremellas of various colours—brown, white, orange, or deep violet. We possess nearly a score in Britain, affecting various vegetation, though two or three would seem to spring from the ground. Like the Algae, they are capable of partial resuscitation by being immersed in water, even after having been kept dry for years. This remark more especially applies to a close ally of the Tremellas, the Jew's Ear (*Hirneola auricula Judæ*). I have met with this singular Fungus on the stumps of Elders. It is of a red-brown colour, like the ear of an American Indian, wrinkled and corrugated, with swelling veins branching from the middle. Autumn is the season of growth, but it continues throughout the winter. I have now before me a specimen of this Fungus that has been perfectly revived, after being kept dry for upwards of two years. *Tremella foliacea*, a rich brown species with a purple gloss, appears with us on old mossy stumps in November. Its curiously puckered growth is sufficiently characteristic of the representatives of the family. It is variable in colour. *Tremella albida* I have noticed on dead Beech branches, bursting through cracks in the bark. It is pure white at first, but changes with age to a dirty yellow. Another of the family, *Tremella mesenterica*, is partial to the Furze, its orange-tufted masses protruding from the dead stems all the year round. It bears a strong resemblance to the human mesentery, hence the name. There is one other I would notice—*Tremella moriformis*—which appears on the ground, and is not often met with. It is not unlike a Mulberry in aspect, though of a purple black. It communicates a purple stain to paper. I believe none are edible.

PETER ISCHBALD.

Hovingham Lodge, York.

Flowers in the Isle of Wight.—I can fully endorse all that Mr. Ewbank has recorded (see p. 511) respecting the beauty of the flowers about Ryde, and the singular mildness of the season there during the months of October and November. When I left Liss, about the 10th of October, nearly all outdoor flowers had vanished; but in the vicinity of Ryde, at St. Helen's, Bembridge, and other places, I was surprised to find what are usually termed "summer flowers" in full bloom at the end of November. A small-leaved Myrtle growing in the little churchyard at Bembridge attracted my especial notice; two particularly fine trees of it were covered with blossom, and a variety of Roses—pale yellow, dark crimson, white,

and all shades of pink—intermingled well with the dark sombre foliage of different evergreen plants that kept watch in that peaceful resting-place. Nearly every grave was a garden in itself. —HILEN C. WATNEY.

LAYING OUT ORCHARDS.

We have often observed a good deal of inconvenience and perplexity in measuring off and laying out orchards, from a want of accuracy at the commencement. The best way of properly laying out extensive plantations of hardy fruits is well told by an able fruit grower in *Rural Affairs*. If the rows are begun crooked, stake after stake may be altered, without being able to form straight lines, and with only an increase of the confusion. If the first tree, in a row of fifty, be placed only 6 inches out of the way, and be followed as a guide for the rest, the last one will deviate fifty times 6 inches, or 25 feet from a right line, even if the first error is not repeated. We have seen large Apple orchards with rows nearly as crooked as this. To say nothing of the deformed appearance to the eye, they prove exceedingly inconvenient every time the crooked space between the rows are ploughed, and every time the ground was planted and cultivated with crops in rows.

Fig. 1.—Common or Square Arrangement.

The most simple and convenient arrangement for orchards in all ordinary cases, is in squares, as shown in fig. 1. But planters are often puzzled to know how to lay out such orchards with trees at equal distances throughout, and in perfectly straight rows. The easiest and most successful mode is first to measure off one side along the boundary, with a chain or tape-line (a chain is best), and drive in a stake perpendicularly at equal distances (say two rods or 25 feet), in a straight line, and at a proper distance from the fence for the first row of trees. Then measure off each end in the same way; and between the two last stakes in these end rows, form another line of stakes like the first, which will be parallel and opposite to it. The more accurately the measuring is done, the less labour will be required in rectifying small errors—no stake should stand half an inch out of a straight line. These rows are represented by the letters *a, b, c, d, e, f, g, h, i*. Then measure off the distance between *a* and *a*, driving in a small stake or peg at each distance of two rods; and then in the same way between *b, b, c, c, &c.* If accurately done, these will all form perfectly straight rows. The holes may then be dug without the least difficulty or embarrassment, and the trees set out. But a difficulty arises, as the stakes must be removed in digging the holes; this is at once obviated by the plan here proposed, by placing the tree in a line with the row of stakes on one side, and with the newly set trees on the other, as the holes are successively dug, and the trees set. These directions may seem quite simple, but for want of being generally understood, a great many crooked lines of trees are seen through the country.

The second mode of arranging trees is in the old quincunx form (fig. 2), which is nothing more than a series of squares laid off diagonally, and has no special advantage to recommend it except novelty.

Fig. 2.—Old Quincunx Order.

The hexagonal or modern quincunx (fig. 3) possesses two important advantages. One is its more picturesque appearance, and its consequent fitness for proximity to ornamental plantations; and the

other is its greater economy of space, as the trees are more evenly distributed over the ground. This is shown in fig. 1, where each

Fig. 3.—Hexagonal or Modern Quincunx.

tree stands in the centre of a circle, surrounded at equal distances by six other trees, and each single circle leaves but little vacant space beyond it. If cultivated with horses, the furrows may be drawn in three different directions, instead of only two, as in the square arrangement. One principal reason why the hexagonal mode is so little adopted is the supposed difficulty in laying out the ground. But, like many other apparent difficulties, it becomes very simple and easy when once understood. To lay off a piece of ground for this purpose, measure off one side of the field at equal distances, as already described for squares, as at *a*, *b*, *c*, *d*, *e*, fig. 4. These distances must be the distance apart at which the trees are to stand, because they form the sides of the equilateral triangles into which

Fig. 4.

the whole ground becomes divided. The next thing is to find the distances, *a*, *f*, *g*, for the line of trees at right angles to the first mentioned row. An arithmetician will easily determine this, for the triangle, *b a f*, being a right one, the square of *b a* (which is 33 feet), subtracted from the square of *b f* (which is 66 feet), will leave the square of *a f*, the root of which, extracted, will give the distances *a f*, *f g*, &c., which is 57 feet $\frac{1}{2}$ inch. Divide this, and the opposite side of the field, therefore, into distances of 57 feet $\frac{1}{2}$ inch, and the side opposite the first, into 33 feet distances, and proceed to stake off all intermediate intersections, as described for squares. If the distances are less than 33 feet, as they would be for any other kind of fruit trees, a corresponding portion is of course to be taken, and which is easily determined as above.

FALL AND RENEWAL OF THE LEAF.

IN Dr. Ascherson's report on the vegetation of the Libyan Desert, published in the *Botanische Zeitung*, there are some interesting notes on the fall and renewal of the leaves of deciduous trees. In our climate (says *Nature*) we have little difficulty in understanding the distinction between evergreen and deciduous trees and shrubs, because the greater part of those that change their leaves shed the old ones in autumn or early winter; and evergreens with flat leaves have them more or less coriaceous. But even with us there is a gradual transition from evergreen to deciduous through *Euonymus europæus* and *Ligustrum vulgare*, both of which have strictly evergreen congeners in *Euonymus japonicus* and *Ligustrum japonicum*. Some few years ago Heffmann started a theory that sempervirence could

be artificially produced, and there is no doubt that climate influences to a great extent the length of the period during which really deciduous species hold their foliage; but it appears far more probable that these are physiological peculiarities not altogether dependent upon climate, as we find evergreen and deciduous species growing in the same regions and under precisely similar conditions. Some evergreens do not change their leaves at all, and even retain them for many years or all their lifetime; *Araucaria imbricata*, for example. *Taxodium distichum* one of the few deciduous Coniferae, offers a very curious phenomenon, inasmuch as the ultimate branchlets are deciduous. The observations chronicled by Dr. Ascherson agree almost entirely with our own experience. On his outward journey he traversed 25° of latitude in less than a month, which gave him an excellent opportunity for studying the conditions of the same species under very diverse climates. Thus, for instance, in the plains of Lombardy many deciduous trees, and especially *Morus alba*, were still partially covered with foliage on the 19th of November, the same species having long previously shed their leaves in Germany. In a similar manner, the Fig trees in Lower Egypt (31° N. lat.) were partially clothed with foliage at the beginning of December, and in Upper Egypt (27° N.) were still in full leaf, whilst already, on the 24th of November, they were quite bare in the Apulian Plain (41° N.). On the 11th of December, the Pomegranate trees in the gardens of Siout were in yellow leaf, and on New Year's Day, 1874, the Apricot trees at Farafreh were still in their prime of green leaf. Hence, one might readily imagine that on approaching nearer the equator these same species would exhibit no interval between the fall and the renewal of the foliage, and thus, to all intents and purposes, become evergreen. But this phenomenon was only verified in the case of the little cultivated Peach trees of the oases, in which it may not be constant. Moreover, the Peach tree shows the same tendency in mild seasons with us. In the oases, at the beginning of March, when the trees began to blossom and make new growth, the old leaves were still fresh and capable of assimilation. All other deciduous trees and shrubs cultivated in the gardens of Kasr Dghakel (25° 45' N. lat.), including the Grape Vine, Apricot, Apple, Pomegranate, Plum, Fig, Mulberry, and Willow (*Salix safsaf*), had lost their foliage on the arrival of Dr. Ascherson, or became leafless before the end of January. It should be mentioned that the fall of the leaf in this region does not proceed with the same regularity as at home, for it is not unusual to see quite naked and fully clothed trees of the same species standing side by side. Again, the presence of abundance of moisture has the effect of enabling the trees to carry their old foliage longer, and put forth their new earlier, than trees growing in drier situations. And some of the Willows growing by water were quite evergreen; that is, after the manner of the Peach trees mentioned above. But the Apricot, one of the most abundant trees, rarely retained even a few scattered old leaves on the appearance of the flowers. The same was observed of the Grape Vine, Fig, and Mulberry. By Feb. 20 the Apricot trees were in full blossom, and by March 10 in full foliage, so that there was only an interval of four or five weeks between the fall of the old foliage and complete development of the new. The Apple and Plum behaved in a similar manner, the Pomegranate was a little later, the Fig next in order, and finally the Mulberry; whilst the same things, in the reverse sense, lost their leaves first. From the preceding notes it seems that the fall and renewal of the leaf is an essential constitutional peculiarity, which is modified by climatic conditions, but not entirely subject to them. A more striking illustration of this fact may be found in exotic deciduous trees planted in Egypt. Dr. Ascherson noted more particularly the summer fall of the leaves of *Poinsettia palcherrima*, a South American shrub, and *Albizia lebbek*, a native of the East Indies. The former is in the full splendour of its inflorescence in December, and quite leafless in April, remaining so, it is said, until the autumn. The *Albizia* is extensively planted as an avenue tree. It sheds its foliage in April, but soon renews it. Both of these plants lose their leaves in their native countries during the dry, and renew them with the opening of the rainy season.

Poisoning Rats.—Will some one who has tried Messrs Rollison's *Cantharikopho* for poisoning rats tell me if they got rid of the vermin? During this last month rats have found their way into one of our propagating houses, doing great damage. My employer bought me a shilling box of *Cantharikopho*, which I spread thickly on thin slices of bread, cut them into small pieces about 1 inch square, and placed them in and about the rats' holes. Instead of the *Cantharikopho* poisoning the rats, however, they appear to be very fond of it; they carried away the pieces in question as fast as they were laid down. Last Friday night I was fortunate enough to catch a large rat in a wire cage trap, and for three days I fed it with

bread thickly spread with *Cantharidopho*. I gave him water to drink, and at the end of the third day the rat was as lively as he was the day on which I caught him. In order to destroy him, ought I to have given him the box as well as the *Cantharidopho*? I think Messrs. Rollisson quite right in stating on the tin box that there is no bad smell from the dead bodies?—W. BALDERSTONE, *Tunbridge Wells*.

ADELER'S GRAPE VINE.

I HAVE not been very successful (says Max Adler in the *Danbury News*), with my experiments in Grape culture. I bought a Vine some time ago, and the man who sold the cutting to me, enjoined me to be careful to water it thoroughly every day. I did so but it didn't seem to thrive. One day I asked my neighbour, Pitman, what he thought was the matter with it, and when I mentioned that I watered it daily, he said, "Good gracious, Adler, that'd kill anyone! A Grape Vine don't want any artificial watering." Then he advised me to discontinue the process, and to wash the Vine with soap-suds, to kill the insects. My anxiety to know why it didn't thrive was relieved some time afterwards by over-hearing a man remark that "some men killed their Grape Vines by their stupid foolery in puttin' soap-suds on 'em." He said that all a Grape Vine wanted was to have the earth around it loosened now and then with a fork or spade. Then I began to dig around my Vine every morning. But one day, while engaged in this exercise, Cooley came and leaned over the fence, and said—"Adler, you'll kill that there Vine if you don't stop diggin' at it. Nothin' hurts a Vine wuss than disturbin' the soil around the roots. Now mind me, that Vine don't want nothin' but to be trained upon a trellis, an' fastened with wire." I ordered a trellis that afternoon, and tied tender shoots of the Vine to the cross pieces. The job cost me £5. On the following Tuesday I read in my horticultural paper that if a man wants to ruin a Grape Vine the quickest way is to tie it up with wire, as the oxidisation destroys the bark. So I took off the wire, and replaced it with string. I was talking about it to the man who came over to bleed my horse for the blind staggers, and he assured me that there was only one sure way to make a Grape Vine utterly worthless, and that was to run it up on a trellis. In France, he told me, the Vineyard owners all trained their Vines on poles, and that was the right way. So I got the axe, and knocked the trellis to pieces, and then fixed the Vine to a beam pole. Still it didn't thrive very well, and I asked a nurseryman near me to come and look at it. He said he couldn't come, but he knew what was the matter with the Vine as well as if he saw it. It wanted pruning. I ought to cut it down within 10 feet of the roots and manure it well. I did cut it down, and emptied a bag of guano over it; but as it seemed sort of slow, I insisted on the nurseryman coming over to examine it. He said that his fee was a sovereign in advance. I paid him and he came. He looked at the Vine a moment, then he smiled, and then he said—"By gum, Adler, that isn't a Grape Vine at all! It's a Virginia Creeper." So I have a kind of knocked off on Grape culture, and am paying more attention to my Cabbages.

The New Pelargonium Society.—I do not think that I shall join this society; it would be like sitting at a feast consisting of one dish without seasoning. If Mr. Barr's proposed society means to include everything outside the pale of *Pelargoniums*, its comprehensive character will secure my adhesion. Surely an enlightened floricultural public can tell when it sees or possesses a good *Pelargonium*, without the necessity of the certification of the fact by a society of raisers and growers, who can push their favourite productions before the world with scarcely the chance of contradiction or objection. One thing alarmed me very much in a recent article on the hybridisation of *Geraniums*; it was the information that a learned gentleman who has assisted in bringing a vast number of miserable, degenerate, and hideous *Ferns* into being, giving them corresponding names, has tried his hand at *Pelargoniums* with much the same result, decrepitude and misery being the apparent result. Is it not time that there should be a society for the prevention of cruelty to plants? The tendencies of communities of the present day is to establish societies for the relief of the afflicted; instead of doing anything to increase the development of that scarlet fever that has for so long a time afflicted gardens, would it not be better to institute a hospital garden for the rehabilitation of declining favourites? For such an establishment I should like to recommend the *Calceolaria*, a poor plant whose constitution has been sadly shaken by excesses; and the *Verbena* would also be a fit subject for such an institution. While on this floricultural topic, let me add a protest against the fashion of giving fancy flowers names that convey no idea or information; indeed, I trust, in many cases they are not meant to be descriptive, or poor Mrs. L., marked as rosy-purple,

might take exception to it, and if I were Mrs. G. I should not like to be put down amongst the purplish-crimsons; to be described as bluish-pink is not a recommendation for fair Miss S.; and stalwart Mr. H. may reasonably object to be placed amongst the bright scarlets. If this fashion goes on our catalogues will be a list of the names of county families. Let Mr. Barr go against this, as well as the Scarlet Fever Society, and many will join him.—WALTER IRVINE, *Birchwood*.

NOTES AND QUESTIONS.

[The following notes and questions came to hand, or were answered, too late for insertion in their several departments.]

King Koffee Savoy.—Through the kindness of Mr. Harrison, of Leicester, I am able to offer an opinion respecting this new Savoy. I have this day had it cooked, and it is certainly a very excellent variety, being mild, with a marrow-like taste, altogether well worth cultivating. Its small heads sit close to the ground; so dwarf is it, indeed, that it need not be planted farther apart than a foot each way.—R. GRUBB, *Burghley Gardens, Stamford*.

Wiring Fruit Walls. A. F. A good distance apart for Peaches and like fruits is from 5 to 6 inches, and for Pears and other trees trained horizontally, 10 inches. If the spur system of training the Peach were adopted, as in France, the wires need not be closer than 18 inches. For shoots trained vertically, sticks half-an-inch square will do, tied or wired to the horizontal wires. Ordinary Willow rods will answer the same purpose.

Planting Pear Trees.—I have a south wall, 80 feet long, to plant this season with Pear trees, and the varieties wanted are late ones. I have selected three kinds, viz., *Burré d'Anjou*, *Gloire d'Orléans*, and *Bergamotte d'Esperance*. Now, if I plant what are called maidens, it will be five years before I get my fruit. I therefore wish to have the opinion of your readers on the method which I propose to follow, and which is, to buy pyramids, plant them 4 feet apart, close to the wall, and prune them by summer pinching instead of the knife. In this way I expect to get a crop the second year.—ENQUIRER.

Filbert Culture.—The Kentish mode is to train the plants up with a single stem of less than a foot in height, after which the branches are trained outwards by being tied to a wire or other hoop, so as to give the tree a basin-like form. All shoots rising from the centre are removed, very often by being pulled out in summer. The advantages of this basin shape are that it enables the sun to shine on the centre of the plant as well as on the sunny side of it, and a full-grown plantation of several acres may often be seen showing trees fully 15 feet in diameter, and not more than 5 feet high at the outside tips. Severe pruning is adopted, and all suckers are carefully removed. The small wood of the previous year's growth produces the fruit, and short spurs of these are only left in winter, all the gross shoots being entirely taken away.

Window Plants refusing to flower.—1. I have a plant in my drawing-room of *Daphne indica rubra*, which, although covered with flower buds, refuses to open them. It has plenty of light, and air, and warmth, and is regularly watered about twice a week. I cannot find an insect upon it, but the leaves insist upon turning yellow, and gradually dropping off dead. It is getting very bare. Is this the habit of the shrub? 2. I have also two plants of the white *Boronia*, covered with flower buds, they also remain closed, and I refuse to come out. They have all the care and attention possible, but the leaves are shrivelling and drying up, and the plants seem in a fair way for death. They are also, with the *Daphne*, in the large bay window of my drawing-room?—H. B., *Woburn*.

Nominal Sizes and Comparative Capacities of Scotch and English Pots.—In emptying some fine pots the other day, among which were several Scotch 10-inch pots—so-called and sold as such—I had the curiosity to measure their actual capacity compared with our 12-inch ones, made and in general use about here. The dimensions were as follows:—Scotch 10-inch pots, average width, 9½ inches; depth, 12½ inches. English 12-inch pots, average width, 10 inches; depth, 12 inches. These Scotch pots were made in Glasgow, and sent to me for 10-inch pots, and excellent pots they are; but, as regards capacity, it will be seen from the above figures that they are, as nearly as possible, equal to our 12-inch pots, and, of course, much larger than our 10-inch ones. In Scotland 10-inch pots are made after the pattern of the old perpendicular Hyacinth pots.—A PINE GROWER.

Positions for the Jasmine-like Solanum.—Having seen *Solanum jasminoides* flourishing outside in a neighbour's garden in the south of England, and having obtained a nice young plant of it, I should be obliged by your informing me whether or not it will succeed in the Midland counties if planted in the open air, and, if not, in what position it succeeds best in a greenhouse or conservatory, together with the soil best suited for its culture.—AMATEUR. [Your plant might succeed out of doors, but the best position for it would be the back wall of a sunny greenhouse, conservatory, or corridor, where it would get its wood well ripened. It likes a good deep loamy soil, enriched with well-rotted dung or leaves, and plenty of water at the root when making its growth. It is rather subject to insect pests when grown indoors, and to prevent these making their appearance, syringe the plant now and then with clean rain water.]

Libonia puerhosiensis.—This comparatively new *Libonia* is the result of a cross between the old *L. floribunda* and *Sericographis Giesbreghtiana*. It is deserving of extensive cultivation for late autumn and winter decoration, being of easy culture, and blooming at a time when flowers are not over plentiful. Cuttings of it put in early in spring strike readily; pot them in small 60-sized pots, and when these are full of roots pot on into 4½'s, putting a single stick to the main stem; place them in heat again till fairly established in the new soil, and grow them on all summer on shelves in a temperate house or close frame near the glass. Syringed daily, these will form beautiful, compact, natural, pyramidal plants by the end of September. If placed then in a house with a regular temperature of about 50°, they will commence flowering by the middle of October, and will continue in bloom for two months or more, forming objects of great beauty for the conservatory or dinner-table, and relieving the sameness of the usual *Chrysanthemum* display at that time of the year. The soil which it likes best is a mixture of tolerably rich loam, leaf mould, manure of equal parts, with a little sand. Although it is well to reduce the supply of water, with plenty of air to ripen the growth towards the end of September, it does not require that preparation and care that is necessary in the case of *L. floribunda*, and it is infinitely more beautiful, and quite as profuse in flowering as the best prepared plants of that variety could be.—W. S., *Birmingham*.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

EMBELLISHMENT OF GLASS-HOUSE WALLS.

IN many instances there is room for improvement in the treatment of the indoor wall surface of both plant and fruit-houses. Flowers and foliage for room and table decorations are always in demand, and the utilisation of unsightly bare walls under glass would doubtless tend to increase the supply. For covering the back or other walls of lofty cool conservatories, the *Camellia*, for striking and permanent effect, is unrivalled. I have often thought, when looking at the weedy character of the usual occupants of such walls, what a change would take place in a few years were they planted with a good selection of *Camellias*. It often happens that, in such positions, only a subdued light reaches the base of the wall, and most of the plants of a climbing or semi-climbing habit rush up to the top after the light, and the lower part of the wall is left bare, or, at least, only thinly covered. The *Camellia*, when planted out in a good border, will thrive and flower in a position, as regards light, where other plants (except, perhaps, the *Myrtle*) would only have a lingering existence. Of course, to cover a wall from 12 to 15 feet high with *Camellias* will take time; but every year they will gradually creep higher, and improve in appearance; and, when at last the wall is covered and the plants in flower, what a grand display will be the result! Even though scentless, the flowers are so brilliant and varied in colour, from the purest white to the darkest crimson, as to be altogether matchless. Where is the plant that will yield so much beauty for so many months in the year, and for so little trouble, as the *Camellia*? and, if the flowers are carefully mounted on wire, they will last a long time after being cut at this season of the year. I have a *Camellia*-covered wall in my mind's eye that I had charge of years ago, where flowers could be had in abundance from November till May—and such flowers—not like the small thin-petalled starlings often seen growing on plants in pots. There is no question, I think, that *Camellias*, planted out in a good border, produce the finest flowers; and, although the bush form is the natural habit of the plant, yet, if planted out in a young state against a wall, it submits to training as readily as any climbing evergreen; and, if early, medium, and late-flowering varieties are selected, flowers in abundance may be obtained from a wall for at least six months in the year, and that, too, at a time when flowers are most valuable. There is, I know, in most places, a demand for flowering plants of a manageable size in pots; and *Camellias*, to meet that want, must always, to a certain extent, be grown in pots; but that need not preclude those who have bare walls in not over-light situations from planting them with *Camellias*, for the sake of their beautiful flowers, for cutting for room decoration, and for the charm imparted to a cool conservatory by having such a wealth of glossy foliage and bright flowers as a background. In planting out *Camellias*, and hard-wooded plants generally, deep planting should especially be guarded against; for, in making new borders that will, for the most part, be composed of fibrous materials, decomposition and settling will go on for years, and the plants gradually, but almost imperceptibly, subside. When this takes place, the proper remedy is to lift the plants, make up the border, and re-plant, when no harm will follow; but I have met with instances where the borders had been gradually made up with fresh soil, without lifting the plants, and the accumulation of soil round their collar brought on a sickly unhealthy appearance, which was speedily followed by death; and, doubtless, some cause other than the true one was assigned for the disaster. I do not think, as regards soil, there is anything better for *Camellias* (if permanent effect is aimed at) than a rich, turfy, rather sandy, loam. If at all adhesive when the fibre in it decays, it will probably become too close and heavy, and although *Camellias* enjoy abundant supplies of water, still, anything in the shape of stagnation at the roots must be avoided; therefore, if the loam is at all heavy, peat, or thoroughly decayed leaf mould, with a

proportion of sand, and lumps of charcoal to increase its porosity should be added, but, in using leaf mould, unless care is used to have none but what is thoroughly decayed, *Fungus* may be introduced amongst the roots that may be productive of serious injury to the plants. I have also, on several occasions, seen the same result follow the use of peat, in which very small particles of the rhizomes of the common Brake Fern, or little bits of the root of the common Heath, had been left in the soil. Therefore, for making *Camellia* borders, if good loam can be obtained which does not contain lime beyond the small average amount usually found in all soils, I should recommend its use in preference to composts of all kinds, and trust to liquid manures, and especially that made from soot, to give strength and vigour when required. As wall or pillar plants for a cool house *Myrtles* might be more extensively used than they are; when planted out they grow rapidly, and their sweet white flowers are exceedingly beautiful. Sprays of glossy-leaved sweet-scented *Myrtle* are very desirable for mixing with cut flowers either in the drawing-room vase or in bouquet making. *Habrothamnus fascicularis* and *elegans* are free-growing and free-flowering plants, of semi-climbing habit, well adapted for covering walls, pillars, or arches in a cool conservatory, as is also the *Cytisus racemosus*, which, when planted in a border of loam, assumes an almost perpetual flowering habit. Many other plants might be mentioned, such as *Magnolia fuscata*, which, although of slow growth, makes rather a desirable wall plant, especially for low walls. In a rather dark shady corner, *Ceanothus puniceus* would be at home, as it is rather subject to attacks of red spider when the sun shines full upon it. *Abutilon Thompsoni* makes a grand wall plant, growing as freely as its parent, the old *Striatum*. I may say, several years ago, I obtained seedlings from this identical with *Striatum*, and so I suppose *Thompsoni* to be a variegated sport from that old variety. In warm light houses, few things can equal the *Luculia gratissima* for covering walls. The *Heliotrope*, also, is a good subject for a light position, as, by judicious pruning back, it may be in bloom at any season of the year. I once had a wall covered with it, that I always cut back in July to get a new flowering growth for autumn and winter. *Fuchsias*, also, when planted out and pruned back in July, will make a new growth and bloom beautifully through the autumn and winter months. *Fuchsias*, however, attain their greatest perfection when trained along the tie-rods supporting the roof, as then they entirely hide their supports, and produce a wondrous wealth of gracefully-drooping floral beauty, that must be seen to be adequately appreciated. Oranges and Lemons—in fact all the *Citrus* family—do well in loam and planted against a wall, in a warm house, and I have seen good crops of, at least, useful fruit produced in this way. These should, however, be planted out when young, and when the branches are pliable, so as to be easily got into shape, without having recourse to strong ligatures, which would have a tendency to check the proper circulation of the sap. There are various ways of clothing the back walls of Ferneries and stoves with Ferns and fine foliage and creeping plants; and, when so treated, a large collection of plants may be grown in an interesting manner in a comparatively small space. Supposing it is desired to cover a wall—at the back of a Fernery, for instance—in which case I will assume the house to have a span-roof running east and west, the back wall being, perhaps, 6 or 8 feet high, and, of course, on the north side. I am only supposing this height, as for my purpose it does not matter whether it is more or less. The wall, in the hottest part, at least, of the day, would be shaded, and would, in consequence, be the dampest shadiest position in the house, eminently suited for flower culture. One mode of planting such a wall would be as follows:—Run parallel wires, tightly strained, 6 inches from the wall, and the same distance apart, to form a support for Moss, Ferns, and soil, which should be principally composed of peat, with some charcoal and pieces of freestone intermixed. I think I need scarcely enter into details, as a small amount of ingenuity, when accompanied by taste, will plant the surface of such a wall with Ferns, Club Mosses, &c., so as to produce a charming effect with the surface neatly Mossed over. *Begonias* of the variegated section might also be introduced with *Fittonias*, *Eranthemums*, *Sonerila margaritacea*, *Cissus*

discolor, and *Panicum variegatum*, but the stove plants, of course, would only be introduced into a tropical Fernery. Another way of making a Fern wall may be just briefly glanced at; and, as this will be a more elaborate affair, it will consequently be more expensive. In the first place call in the bricklayer, and have a series of small brick arches run all along the base of the wall. On the first series, run a second just a little narrower, and on the second a third, and so on till the top of the wall is reached, the arches gradually decreasing in size, so as to be narrowest at the top. If the arches are one brick thick, that will be quite strong enough. It is not necessary that the arches, in any one series, should be all alike, as, if diversity of outline is sought for, it may be obtained by varying the size. This system of brick arches will form the base or foundation of the structure, and may be dressed in any shape desired, leaving plenty of pockets to hold soil to grow Ferns and other plants. The mode of dressing and hiding the brick-work is altogether a matter of taste, and may be done either with virgin cork, or spar, or red sandstone, worked up with cement, avoiding as much as possible all formality. Of course, all the brick-work will be covered with whatever material it is decided to use, as the main object of using brick arches at all is to make sure of a supply of moisture and soil. I believe a good case might be made out for the extended cultivation of Oranges, Lemons, Guavas, Cape Gooseberries, &c., on the back walls of Vineries and other fruit houses; but in all cases where the walls are used in this way they should be well painted and wired for training, and once a year, usually at this season, the plants should be unfastened from the wall, which should be washed with a solution of soft-soap, or some other insecticide, to keep down insects.

E. HOB DAY.

THE BEST WINTER-BLOOMING LÆLIAS.

Most of the plants of this genus are beautiful, but I find *L. autumnalis* and *L. anceps* the best for the supply of cut flowers, a purpose for which they should be grown in every plant-stove. *L. autumnalis* grows well on a block, and does not like much shade, indeed a Vinery suits it admirably when growing, the partial shade afforded by the Vine leaves being amply sufficient. *L. anceps* grows well in a peaty compost, and a broad pan is best, as more space is thus afforded for its creeping rhizomes. It also affects a more shady and moisture-laden atmosphere. One of the great essentials to the welfare and vigour of all the winter-flowering Lælias is a free circulation of air, both by day and night, during summer and during mild bright weather in winter. Their flowers will also be found to keep fresh much longer in an airy atmosphere. I have two large masses of *L. autumnalis* now in bloom, one with ten and the other with fourteen strong spikes, and I consider it one of the most beautiful of all winter flowers. Its soft rosy-lilac white-throated blossoms are invaluable for bouquets, and look almost blue when contrasted with orange-yellows, but with white Bouvardias, Jasmine, Stephanotis, Tuberoses, and pale yellow or salmon-tinted Tea Roses, they have a fine effect. Seen under artificial light they look very striking, the cellular tissues of each segment glistening like hundreds of tiny little brilliants set in the softest and most delicate rosy coral. Cut spikes last three weeks or even longer in the drawing-room vases. I have three large pans of *L. anceps* (an Orchid which every beginner in Orchid culture should try his hand at, and the result is sure to please him), and these collectively bear forty-six spikes, most of which are producing three and some four flowers each. The flowers are large and of more decided colours than the last-named, but for cutting they are very useful, and are equally permanent when cut. The rich velvety crimson of the tip, contrasted by a broad streak of the richest golden-yellow, is particularly beautiful. The five plants I have mentioned form the gems of my collection, and I think all the more highly of them because I grow them in Vineries most of the year, and shift them to a tiny little plant-stove when in flower. I have also plants of the creamy-white flowered *L. alba* and the broad-petalled lilac-flowered *L. furfuracea*; these, however, although worth adding to a general collection, do not flower freely enough to merit general cultivation, where, as, in my case, space is limited. I had a large plant of *L. superbians*, which for years only bore one solitary flower-spike, I, therefore, discarded it, thinking that I might apply the room which it occupied to better purpose. *L. acuminata* is another very pretty species, bearing a spike of snowy white flowers, the most distinctive feature being a deep purplish-crimson blotch in the centre of the lip.

J. G. H.

NOTES OF THE WEEK.

— ADVERTING to some expeditions he made during the year, Baron Mueller, in a recent report, alludes to specimens of *Eucalyptus amygdalina*, 400 feet in height, as also to *Festuca dives*, a stately Grass, often 12 to 17 feet in height, growing in Fern-tree gullies. Let us hope this may prove a worthy addition to the Pampas and the New Zealand *Arundo conspicua*.

— MR. TYERMAN, writing to us from Cornwall, states that he has *Grevillea rosmarinifolia* beautifully in flower in the open borders, and adds that it is worthy of a prominent position in all moderately mild situations. *Fagelia bituminosa* has also proved itself to be quite hardy in Cornwall, and retains its leaves well during winter, a fact worth knowing, as few more interesting plants are to be found amongst climbing Leguminosæ.

— AMERICAN CRANBERRIES, of great size and highly coloured, now find their way into our markets, and may be seen exposed for sale in the shops of provincial fruiterers. Their cultivation is particularly attended to in America.

— ON more than one occasion we have alluded to the large-flowered silvery-white Immortelles, used so largely by the Covent Garden florists in the manufacture of wreaths and other ornamental designs. It appears to be a distinct form of *Helichrysum*, far superior to any now in cultivation in Europe.

— A PROPOSITION has, we learn, been set on foot by Sir Robert Christison with a view to adding 20 acres to the Edinburgh Botanic Garden, for the purpose of an arboretum, where the cultivation of our ordinary forest trees, the conditions of success, the causes of failure, diseases, their prevention and cure, might be conveniently and advantageously studied.

— A PORTION of Tooting Common is to be immediately converted into a public park and recreation ground, the claims as to the rights of pasturage and other privileges having been settled. The manorial rights, too, have been purchased and made over to the Metropolitan Board of Works as conservators, and that body will at once proceed to lay out the ground as a park, which it is expected will be opened to the public in spring or early next summer.

— THE council of the Society for the Promotion of Scientific Industry, the headquarters of which are at Manchester, has decided to give gold, silver, and bronze medals, for excellence and novelty in the various classes of exhibits at the exhibition of implements, machines, and appliances for economising labour, which is to take place in Manchester in 1875. The arrangements for the exhibition are progressing satisfactorily, and space has been secured by many high-class engineering and other firms.

— WE have just seen some charming flowers, sent from one of Messrs. Piesse & Lubin's flower farms near Nice. These consist of Camellias, Tea Roses, Neapolitan Violets, Mignonette, Orange blossom, and other kinds, which, notwithstanding the long journey to which they had been subjected, arrived in London as fresh as if only just cut from the plants. On these sunny farms whole acres are devoted to the culture of sweet-scented flowers of various kinds, from which the odours and essences now so popular are obtained.

— AS is usual about Christmas time the exhibition of choice fruit in Covent Garden has been a very interesting one. Pines, both imported and of home growth, have been excellent as have also been Grapes, especially Muscats of English growth. Among Apples have been very fine specimens of Reinette du Canada and Calville Blanche, two excellent kinds more largely grown on the Continent, and in the Channel Islands, than with us. Easter Beurré Pears have been plentiful, and specimens of Uvedale's St. Germain (Belle de Jersey) have been, if possible, finer this year than usual; they are, however, useless for dessert purposes.

— LILUM NEILGHERRICUM, first brought into notice by Messrs. Veitch, but which has been lost sight of for some years, has just been re-introduced by the Colebeater Bulb Company. In Dr. Wallace's "Notes on Lilies" (p. 51), it is thus described:—"Gathered in the Neilgherries, in the neighbourhood of Ootacamund, at an elevation of about 8,000 feet, by Dr. Wight, Gardner, Thomson, and many other botanists; and northward, in the Mysore territory, by Mr. T. Lobb. The range of form, which it presents, may be seen in Dr. Wight's three figures. It is quite as variable as the Japanese—Chinese sub-species—and though such a striking form, has been almost entirely neglected by cultivators." The Colebeater Company state that, in form, it is similar to *L. longiflorum*; that the flowers have the same substance as those of *L. Brownii*, and that in colour they vary from white to yellow. They mention that it is a difficult Lily to obtain; they have only received a few bulbs of it, and expect no more this season.

— THE word "Pines" was inserted by mistake instead of Planes in our notice of Bedford Square last week.

THE FLOWER GARDEN.

ARUNDO CONSPICUA IN HEREFORDSHIRE.

THE plant, of which the accompanying illustration is a representation, is about five years old. It was planted in a shrubbery border in 1869. For the first two or three years after it was planted it grew rapidly, but produced only a few weakly flower-stems; afterwards, however, when it had established itself and had formed into a large mass, it commenced blooming much earlier, and produced from fifty to sixty flower stems, which lasted in perfection at least three months. Several large plants of this reed may now be seen in the King's Acre Nurseries; the soil in which they are growing is the stiff retentive loam in which Roses delight. They have never received any manure, and the plants are left undisturbed; for, when moved, it is found that they do not flower in the same luxuriant manner for several years afterwards. The *Arundo* generally commences blooming early in July, and lasts until the end of October. The Pampas rarely comes out in full flower before November; the *Arundo*, therefore, while as beautiful when well grown, has a peculiar value in being so early. We are indebted to Mr. Cranston for a photograph of this plant.

NEW TYPE OF PELARGONIUM.

ALL who have taken up the cultivation of the Pelargonium are acquainted with the hybrids produced between the Ivy-leaved and Zonal kinds obtained in England by Mr. Wills and Mr. Grieve. They are aware also that these hybrids appear to support the theory of certain cultivators, inasmuch as those kinds, of which we have any knowledge, and particularly Willsii, Willsii rosea, Emperor, and Dolly Varden, are sterile, and this is all the more to be regretted, because they are superior to *P. peltatum* and lateripes, by reason of their great vigour and abundant inflorescence. Pelargonium raisers will therefore learn with pleasure that a plant of this class has been found in the neighbourhood of Nice, which produces seed in abundance. From what has been stated concerning it, I gather that it was found in a garden near Nice in a border in which were the pale lilac-flowered Ivy-leaf, and the rose, white, and scarlet-flowered Zonals. From what I can judge from the leaves and flowers I have received, it is certainly a hybrid between these two sections, but, bearing a greater general resemblance to the Ivy-leaf than to a Zonal, as it is decumbent; on the other hand the leaves are more like those of a Zonal than the hybrids obtained in England. The flowers are of a very brilliant red, and number from fifteen to twenty upon one umbel. The Zonals have, therefore, had much to do with the fertilisation. What the seed-bearing plant is we know not, and perhaps never shall. It is in the hands of Mr. Charles Haller, of Nice, who will have it for sale in March under the name (an erroneous one, I think) of *Geranium pseudo zonale*. It is an interesting plant to all engaged in hybridising, for, with all due respect to certain theorists, who can say what will come of it? F.

DO VARIETIES WEAR OUT, OR TEND TO WEAR OUT?

By Prof. ASA GRAY.*

THIS question has been argued from time to time for more than half a century, and is far from being settled yet. Indeed, it is not to be settled either way so easily as is sometimes thought. The result of a prolonged and rather lively discussion of the topic about forty years ago in England, in which Lindley bore a leading part on the negative side, was, if we rightly remember, that the nays had the

* In *New York Tribune*.

best of the argument. The deniers could fairly well explain away the facts adduced by the other side, and evade the force of the reasons then assigned to prove that varieties were bound to die out in the course of time. But if the case were fully re-argued now, it is by no means certain that the nays would win it. The most they could expect would be the Scotch verdict, "not proven." And this not because much, if any, additional evidence of the actual wearing out of any variety has turned up since, but because a presumption has been raised under which the evidence would take a bias the other way. There is now in the minds of scientific men some reason to expect that certain varieties would die out in the long run, and this might have an important influence upon the interpretation of the facts that would be brought forward. Curiously enough, however, the recent discussions to which our attention has been called seem, on both sides, to have overlooked this matter. But, first of all, the question needs to be more specifically stated, if any good is to come from a discussion of it. There are varieties and varieties. They may, some of them, disappear or deteriorate, but yet not wear out—not come to an end from any inherent cause. One might even say, the younger they are the less the

chance of survival unless well cared for. They may be smothered out by the adverse force of mere superior numbers; they are even more likely to be bred out of existence by unprevented cross-fertilisation, or to disappear from mere change of fashion. The question, however, is not so much about reversion to an ancestral state or the falling off of a high-bred stock into an inferior condition. Of such cases it is enough to say that when a variety or strain, of animal or vegetable, is led up to unusual fecundity, or size, or product of any organ, for our good, and not for the good of the plant or animal itself, it can be kept so only by high feeding and exceptionable care; and that with high feeding and artificial appliances, come vastly increased liability to disease, which may practically annihilate the race. But then the race, like the burst boiler, could not be said to wear out, while if left to ordinary conditions, and the race allowed to degenerate back into a more natural, if less useful, state, its hold on life would evidently be increased rather than diminished. As to natural varieties or races under normal conditions, sexually propagated, it could readily be shown that they are neither more nor less likely to disappear from any inherent cause than the species from which they originated. Whether species wear out, i.e., have their

rise, culmination, and decline from any inherent cause, is wholly a geological and very speculative problem, upon which, indeed, only vague conjectures can be offered. The matter actually under discussion concerns cultivated or domesticated varieties only, and, as to plants, is covered by two questions.

First, will races propagated by seed, being so fixed that they come true to seed, and purely bred (not crossed with any other sort), continue so indefinitely, or will they run out in time—not die out, perhaps, but lose their distinguishing characters? Upon this, all we are able to say is that we know no reason why they should wear out or deteriorate from any inherent cause. The transient existence or the deterioration and disappearance of many such races are sufficiently accounted for otherwise. As in the case of extraordinarily exuberant varieties, such as mammoth fruits or roots, by increased liability to disease, already adverted to, or by the failure of the high feeding they demand. A common cause, in ordinary cases, is cross-breeding, through the agency of wind or insects, which is difficult to guard against. Or they go out of fashion and are superseded by others thought to be better, and so the old ones disappear. Or, finally, they may revert to an ancestral form. As offspring tends to resemble grand-parents almost as much as parents, and as a line of close-bred ancestry is generally prepotent, so newly

Arundo conspicua in the King's Acre Nurseries, Hereford.

originated varieties have always a tendency to reversion. This is pretty sure to show itself in some of the progeny of the earlier generations, and the breeder has to guard against it by rigid selection. But the older the variety is—that is, the longer the series of generations in which it has come true from seed—the less the chance of reversion; for now, to be like the immediate parents, is also to be like a long line of ancestry; and so all the influences concerned—that is, both parental and ancestral heritability—pull in one and the same direction. So, since the older a race is, the more reason it has to continue true, the presumption of the unlimited permanence of old races is very strong. Of course, the race itself may give off new varieties; but that is no interference with the vitality of the original stock. If some of the new varieties supplant the old, that will not be because the unvaried stock is worn out or decrepit with age, but because in wild Nature the newer forms are better adapted to the surroundings, or, under man's care, better adapted to his wants or fancies.

The second question, and the one upon which the discussion about the wearing out of varieties generally turns, is, Will varieties propagated from buds, i.e., by division, grafts, bulbs, tubers, and the like, necessarily deteriorate and die out? First, do they die out as a matter of fact? Upon this the testimony has all along been conflicting. Andrew Knight was sure that they do, and there could hardly be a more trustworthy witness. "The fact," he says, fifty years ago, "that certain varieties of some species of fruit which have been long cultivated cannot now be made to grow in the same soils and under the same mode of management, which was a century ago perfectly successful, is placed beyond the reach of controversy. Every experiment which seemed to afford the slightest prospect of success was tried by myself and others to propagate the old varieties of the Apple and Pear which formerly constituted the orchards of Herefordshire, without a single healthy or efficient tree having been obtained; and I believe all attempts to propagate these varieties have, during some years, wholly ceased to be made." To this it was replied, in that and the next generation, that cultivated Vines have been transmitted by perpetual divisions from the time of the Romans, and that several of the sorts still prized and prolific are well identified, among them the ancient *Græcula*, considered to be the modern Corinth or Currant Grape, which has immemorially been seedless; that the old Nonpareil Apple was known in the time of Queen Elizabeth; that the White Beurré Pears of France have been propagated from the earliest times; and that Golden Pippins, St. Michael Pears, and others said to have run out, were still to be had in good condition.

Coming down to the present year, a glance through the proceedings of pomological societies, and the debates of farmers' clubs, brings out the same difference of opinion. The testimony is nearly equally divided. Perhaps the larger number speak of the deterioration and failure of particular old sorts; but where the question turns on "wearing out," the positive evidence of vigorous trees and sound fruits is the most telling. A little positive testimony outweighs a good deal of negative. This cannot readily be explained away, while the failures may be, by exhaustion of soil, incoming of disease, or alteration of climate or circumstances. On the other hand, it may be urged that, if a variety of this sort is fated to become decrepit and die out, it is not bound to die out all at once, and everywhere at the same time. It would be expected first to give way wherever it is weakest, from whatever cause. This consideration has an important bearing upon the final question; are old varieties of this kind on the way to die out on account of their age or any inherent limit of vitality? Here, again, Mr. Knight took an extreme view. In his essay in the "Philosophical Transactions," published in the year 1810, he propounded the theory not merely of a natural limit to varieties from grafts and cuttings, but even that they would not survive the natural term of the life of the seedling tree from which they were originally taken. Whatever may have been his view of the natural term of the life of a tree, and of a cutting being merely a part of the individual that produced it, there is no doubt that he laid himself open to the effective replies which were made from all sides at the time, and have lost none of their force since. Weeping Willows, Bread-fruits, Bananas, Sugar-cane, Tiger Lilies, Jerusalem Artichokes, and the like, have been propagated for a long while in this way, without evident decadence. Moreover, the analogy upon which his hypothesis is founded will not hold. Whether or not one adopts the present writer's conception that individuality is not actually reached or maintained in the vegetable world, it is clear enough that a common plant or tree is not an individual in the sense that a horse or man, or any one of the higher animals is, that it is an individual only in the sense that a branching zoophyte or mass of coral is. *Saliciter crescendo*: the tree and the branch equally demonstrate that they are not individuals, by being divided with impunity and advantage, with no loss of life, but much increase. It looks odd enough to see a writer like Mr. Sisley re-producing the old

hypothesis in so bare a form as this. "I am prepared to maintain that varieties are individuals, and that as they are born they must die, like all other individuals." "We know that Oaks, Sequoias, and other trees live several centuries, but how many we do not exactly know. But that they must die, no one in his senses will dispute." Now, what people in their senses do dispute is, not that the tree will die, but that other trees, established from cuttings of it, will die with it. But does it follow from all this that non-sexually propagated varieties are endowed with the same power of unlimited duration that are possessed by varieties and species propagated sexually—i.e., by seed? Those who think so jump too soon at their conclusion. For, as to the facts, it is not enough to point out the diseases or the trouble in the soil or the atmosphere to which certain old fruits are succumbing, nor to prove that a parasitic fungus (*Peronospora infestans*) is what is the matter with Potatoes. For how else would constitutional debility, if such there be, more naturally manifest itself than in such increased liability or diminished resistance to such attacks? And if you say that, anyhow, such varieties do not die of old age—meaning that each individual attacked does not die of old age, but of manifest disease—it may be asked in return, what individual man ever dies of old age in any other sense than of a similar inability to resist invasions which in earlier years would have produced no noticeable effect? Aged people die of a slight cold or a slight accident; but the inevitable weakness that attends old age is what makes these slight attacks fatal. Finally, there is a philosophical argument which tells strongly for some limitation of the duration of non-sexually-propagated forms, one that probably Knight never thought of, but which we should not have expected recent writers to overlook. When Mr. Darwin announced the principle that cross-fertilisation between the individuals of a species is the plan of Nature, and is practically so universal that it fairly sustains, his inference, that no hermaphrodite species continually self-fertilised would continue to exist, he made it clear to all who apprehend and receive the principle that a series of plants propagated by buds only must have a weaker hold of life than a series reproduced by seed, for the former is the closest possible kind of close breeding. Upon this ground such varieties may be expected ultimately to die out; but "the mills of the gods grind so exceedingly slow," that we cannot say that any particular grist has been actually ground out under human observation. If it be asked how the asserted principle is proved or made probable, we can here merely say that the proof is wholly inferential. But the inference is drawn from such a vast array of facts, that it is well nigh irresistible. It is the legitimate explanation of those arrangements in Nature to secure cross-fertilisation in the species, either constantly or occasionally, which are so general, so varied and diverse, and, we may add, so exquisite and wonderful, that, once propounded, we see that it must be true. What else, indeed, is the meaning and use of sexual reproduction? Not simply increase in numbers, for that is otherwise effectually provided for by budding propagation in plants and many of the lower animals. There are plants, indeed, of the lower sort, in which the whole multiplication takes place in this way, and with great rapidity. These also have sexual reproduction; but in it two old individuals are always destroyed to make a single new one. Here propagation diminishes the number of individuals 50 per cent. Who can suppose that such a process as this, and that all the exquisite arrangements for cross-fertilisation in hermaphrodite plants, do not subserve some important purpose? How and why the union of two organisms, or generally of two very minute portions of them, should reinforce vitality we do not know and can hardly conjecture. But this must be the meaning of sexual reproduction.

The conclusion of the matter from the scientific point of view is that sexually-propagated varieties or races, although liable to disappear through change, need not be expected to wear out, and there is no proof that they do; also, that non-sexually propagated varieties, though not liable to change, may theoretically be expected to wear out, but to be a very long time about it.

Layering Wistarias.—Late last spring I layered several long slender shoots which had sprung up from the base of an old plant in my garden. To-day I dug them up, and find that every portion of the Vine covered in the ground is well furnished with roots. The result of a half-hour spent in layering is at least two dozen strong plants. I only mention the fact to encourage others in doing likewise whenever an opportunity presents. The Wistarias are all elegant climbing shrubs, some of them natives of America and others of China. The flowers are Pea-shape, and produced in long drooping clusters. The Chinese varieties bloom very early in spring, before the leaves appear, while the American sorts come on later; therefore, by cultivating both we prolong the season, besides

securing a greater variety of colours. The Chinese varieties are more showy than the American. There are sorts of the former with bluish-purple flowers, another which is pure white, and a new variety, lately introduced, with double flowers. There is also an American variety with white flowers, besides the more common purple and pale-lilac sorts. Any branch or slender shoot will strike root freely if covered with earth; and after one gets a stock plant others may be produced, by layering, to an almost unlimited extent. They are grand plants, and should become more common throughout the country.—*Moore's Rural*.

A NEW HARDY CLIMBER.

(MAXIMOWICZIA SINENSIS.)

AMONG novelties contained in seed catalogues of the present season, this plant is worth notice. It comes from the banks of the Amur, and is perfectly hardy. Judging from dried specimens and a coloured sketch of the fruit now before us, it is likely to become a favourite with all interested in ornamental fruited plants. The flowers, which are borne in axillary clusters, are greenish or creamy-white in colour,

Maximowiczia sinensis.

not at all ornamental; but they are succeeded by bright red or crimson Pear-shaped fruits, as shown in our illustration. The ovate serrate foliage is of a shining green colour, and contrasts well with the glossy fruit. The plant has been introduced to European gardens by M. Otto Pntz, to whom we are indebted for the above description.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Hepaticas: Mrs. N. O. These grow best in rich peat or other light soil, and a somewhat shady and sheltered position; but they will also succeed in any good garden soil, and in more exposed positions, provided it be not too hot and dry. *H. angulosa* will thrive perfectly in sandy moist soil in a shrubbery of young trees.

Plants for Shady Situations.—Will a Clematis succeed on a very dry and shady rocky in peaty soil? Ferns will not do there, as it is too dry. If you do not think a Clematis will do, please suggest something else.—E. L. J. [There is no plant that enjoys sunshine and light more than the Clematis, and I do not think it would flower in the situation described. Perhaps some of the finest ornamental varieties of the Ivy would be the best plants with which to cover such a rookery, for their spreading roots would soon find moisture enough to keep them growing. Ferns do best in the shade, and might be made to grow with frequent artificial waterings, some strong loam being added to the peat to retain the moisture.—W. T.]

Californian Lilies.—For several years we have been purchasing California and Oregon Lilies, and must now have from five to ten thousand. We have never dared offer one for sale, because we did not know what to name or how to describe them. We have obtained half a dozen varieties under one name, and half a dozen names to bulbs that were all alike. In our necessity, we wrote to Henry A. Bolander, Esq., Superintendent of Public Instruction, and connected with the Geological Survey of the State of California as botanist, and from him we learn that this confusion of names is not accidental, but designed, and for the purpose of fraud, and that "there are but four species of Lilies in this wide western coast. It is true they vary, but in no case sufficient to warrant a new name; in no case is a reliable distinction to be made."—*Fick's Guide*.

THE KITCHEN GARDEN.

ONIONS IN LONDON MARKET GARDENS.

WHERE this crop thrives well it is a very remunerative one, and about London it is grown to perfection in fields, sown broadcast. To those who are accustomed to grow Onions in beds and in lines, this plan may seem antiquated, but those who object to it have only to take a walk in July or August through the Fulham, Chiswick, Deptford, Woolwich, or Mitcham market-gardens to be convinced of its utility. The varieties of Onions grown in these localities are mostly the Reading, Deptford, white Tripoli, and Lisbon. The Reading or white Spanish, as it is commonly called, is a large, somewhat flat, and pale-skinned Onion, having a mild flavour, but it is not a good keeper; consequently it is largely sown in spring for affording a supply between Midsummer and Christmas. The Deptford is one of the best Onions that can be grown, and, as it keeps well, it is largely sown in spring for yielding a supply of ripe bulbs in the succeeding winter. Its skin is of a brown colour, flesh firm, flavour strong, and its keeping qualities almost better than those of any other sort. In shape it varies from flat to globular. The Lisbon and white Tripoli are sown in August for spring use, when, on account of their long white necks, they are much preferred to any other sort; and whatever portion remains unsold in spring is transplanted, when they yield large soft bulbs for immediate use. Of the silver-skinned, considerable quantities are grown in the neighbourhood of Sandy, in Bedfordshire, for pickling purposes. The main spring sowing is made of the Deptford and Reading Onions as soon after the middle of February as the condition of the soil and weather permits. If the seed be really good, Mr. Myatt, of Deptford, informs me that when he sows broadcast he uses 9 lbs. to the acre. If they were sown in lines he would only use 8 lbs. to the acre, but the additional pound in the broadcast sowing he considers well spent in the amount of labour saved over that expended in sowing in lines. Considering the regular distances at which broadcast Onions stand apart all over the field, the produce is more than from a field of Onions sown in beds or in lines. I therefore consider broadcast sowing the best for market purposes. The soil for Onions is made rich and is well pulverised, and is, if possible, that which has been trenched and laid up in ridges during the winter. In February, as soon as the ground is in good workable condition, break up freely; the ridges into which it was thrown in winter are levelled, and the whole surface is firmly trampled or rolled. The seed is then sown and raked in, and all is finished by another rolling. Nothing is placed in the ground in the way of a catch crop from the time of sowing to that of harvesting; indeed, Onions are one of the few crops that are the sole occupiers of the ground during the whole period of their growth. The seed takes a considerable time to germinate; but if the ground is clean and well tilled, weeds will not appear much sooner than the Onions, or at least not so thickly as to choke them. As soon as the Onions have fairly come up, however, women or men, accustomed to Onion cleaning, are set to work amongst them. These operators are furnished with the short-handled 2½-inch wide hoes, with which they hoe down the weeds and thin the crop with wonderful certainty and expedition. The field is marked off into strips for the guidance of the hoers, to each one of whom there is a space of a couple of yards given, so that were four cleaners employed the strips would each be 8 yards wide. People accustomed to this work do not trample carelessly about; nor, indeed, can the crop be damaged materially by doing so, for the Onions that are thus prostrate to-day are nearly erect to-morrow. Each plantation is generally cleaned by this means three times during the season, the last cleaning being made about the end of June or early in July, and any big weeds that appear after that time are pulled out by the hand. As fine a crop of Onions as I have seen was in a field near the left bank of the Thames, in the gardens of Mr. Jessop, at Chiswick. Mr. Abernath, of Mitcham, informs me that in a field of Onions he had two years ago, the produce was about 16 tons to the acre, and he got £12 for each ton, thus realising a gross sum of £192 per acre; but when labour, manure, and rent, are deducted from this, the net sum would be much less. Mr. Bagley, of Turnham Green, had a splendid crop of Onions, large and equal, and these he sold on the ground as they stood to a greengrocer, who harvested them himself in the end of August, for £10 per acre. This price is a much more likely sum than that in the preceding case, for which I have only the grower's word. Towards the end of August or early in September, the Onions, being ripe, are harvested when dry. Those that are green and thick-necked are laid aside for immediate sale, but the firm and sound bulbs, particularly of the Deptford kind, are either cleaned of any loose scaly skins and spread out a few inches deep over the floor of a loft, or tied into bunches and strung in twos over poles or on pegs in a loft or shed, so that they can be marketed at any convenient season during the winter and spring. The autumn

sowing is made on ground cleared of Cauliflowers, Cabbages, or other early crops. The first sowing, consisting of the white Spanish, white Tripoli, or Lisbon, is made in the last week of July, for drawing in a young state from September onwards, but the main sowing is not made till about August 25. The autumn sowings are always made in beds about 5 feet wide, with 1 foot alleys between them, and the seeds are covered deeper than those of the spring sowings. Autumn sowings of Onions are never made broadcast on fields, as they must be weeded, not hoed, in the process of cleaning. The hoeing would thin them too much; as they are only required for drawing when young, they do not need to be more than one-third of the distance asunder required in the case of the summer Onions. They are weeded soon after they come up, and once, or perhaps twice, during the winter time. Weeding is performed by women in dry weather, each of whom takes a small round basket to put the weeds into rather than throw them on the alleys. In marketing these Onions they are cleared off the beds in large patches, and not by picking out the strongest and leaving the weakest, as is generally done, and they are washed, which makes their long white necks look clean and inviting. If a portion be intended for transplanting, a piece of well-prepared rich ground is made ready for them, rolled firmly, and lined off into rows about 9 inches apart, and into these lines the young plants are dibbled about 6 inches apart. W. F.

WINTER SPINACH.

SPINACH is largely grown in most gardens for autumn, winter, and spring use, but it is not cultivated for market purposes in summer, owing to its liability to "run" almost as soon as the seed has germinated. The round-leaved sort is that which is used for spring sowings, the first of which is made in February, a second about the 1st of March, and another sowing or two at an interval of three weeks or thereabouts, just as empty space and convenience permit. Spaces under trees are often covered with Spinach sown broadcast, and, as the trees are not furnished with leaves, they do not shade the plants. Open fields are also often sown with Spinach in beds, which are covered by throwing soil over them from the alleys; on these beds Cauliflowers are also planted, at the usual distances apart. By the time the Spinach has come well up the Cauliflowers will have become nicely established, so that the Spinach, which, as soon as ready, is removed for market, does not injure the Cauliflowers much. When the Spinach is removed, the Cauliflowers are permitted to have all the space; consequently the ground is gone over, hoed, and allowed to rest for a few days, when some soil is drawn to the Cauliflower plants. The latest spring sowings of Spinach are made on a damp cool piece of ground, provided such can be obtained, as, thus circumstanced, better leaves are produced in hot weather than on dry and warm soils. In July, if the weather is moist, a sowing of the round-leaved variety is usually made on a spare piece of ground, for autumn use. The first autumn sowing is, however, generally delayed till August, early in which month a large sowing of the Prickly-seeded or Flanders is made broadcast on fields or in rows about 8 inches apart. Mr. Myatt prefers the Flanders, and, indeed, most growers also do so, on account of its large fleshy leaves and hardy constitution, and it sells more readily than the prickly sort. By sowing on the 12th and 25th of August and the 14th of September, Mr. Myatt keeps up a succession of Spinach from October till May. Although during winter but few leaves are produced, the earliest sowings yield freely before then, and the two latter abundantly in spring. Coleworts are frequently planted in a field of late Spinach, at 3 or 4 feet apart. In damp winters a large proportion of the roots may die, but in ordinary winters they retain their vitality, and produce abundance of large fleshy leaves in spring. No care is taken with this crop from the time of sowing till gathering, beyond hoeing and thinning once or twice. Spinach for market is packed firmly in round baskets, and also in bampers of any size convenient for handling. W.

SINGULAR INSTANCE OF GROWTH-FORCE.

HAVING observed that Beans, Squashes, and other seeds, would exert a great lifting force as they pushed their way out of the ground, President Clark undertook, last summer, to see what a soft vegetable growth could do. Though he had noticed bricks and stones upon sidewalks pushed away from their places by the roots of trees, and had read the story of an 80 lb. flagstone raised by three large Mushrooms, he had no conception of what a soft vegetable could lift till he experimented upon a Squash of the *Cucurbita maxima*, or Mammoth, variety. French Pumpkin is another name for it. The texture of this Squash is soft and watery, and it is of rapid growth and great size; in one instance in England it is said to have reached 246 lb.

To give the Squash a fair chance, Mr. Clark prepared beforehand. He built in a glass-house a box 4 feet wide by 50 long, and filled in rich earth 6 inches deep, and planted the seed July 27. It came up in due time, and grew apace. In watching the roots of this plant, it was found that it sent down a primary root 4 inches deep, and then lateral rootlets that travelled through the soil, when the aggregate of all their ramifications and their sub-divisions were counted, at the rate of 2,000 feet per day. The whole of the roots, counting those which were sent down from the nodules and appeared first as tendrils, reached the enormous length of 80,000 feet, equal to 15 miles if placed in one straight line. It threw out several branches from the main stem, and sent up flower-stems, every fifth one of which was a pistillate flower. One of these pistillate flowers was fertilised, a Squash grew, and, at about one month from the time of planting the seed, it was thought to be large enough to break to harness for pushing. That it should not yield from below, a hollow bed fitting the form of the Squash was placed under it and firmly supported. A harness was made of three strong flat iron bands, bent to the shape of the fruit and fastened together. Above these bands, and resting upon their middle and most elevated part, was raised and fastened a long sharp edge of steel for a pivot to balance a lever on. One end of a strong iron lever was made fast a foot from the pivot, and the other end reached several feet the other side. Weights were hung on the long end of the lever, and left for the growing Squash to hoist. The iron lever soon failed to hold it down, and bent and broke. This was replaced by a larger bar of steel. When this failed, a strong chestnut lever was substituted, and broke. Then a tough oak lever, and, finally, a chestnut fence-post, 9 feet long, and 5 by 6 inches where it rested on the pivot. But lo! this strong timber, loaded on the long end with six anvils and seven pairs of chains, cracked under the tremendous pressure exerted by the growth of the soft Squash. The weight it was lifting at this time, 24th of October, which had been gradually increasing from 22nd of August, was 4,120 lb. On the 31st of October the lever failed and was strengthened with a piece of an old tire of an ox-cart wheel. The Squash continued to grow, but the harness-irons bent so as to break the shell at the corners, and the weights were therefore removed on the 7th of November, 1874. Mr. Clark thinks there can be no doubt that the expansive force of the Squash was equal to lifting the 5,000 lb. if it could have been properly distributed over the surface. After being freed from its labours the distinguished Pepo was honoured with a presentation to the State Board of Agriculture of Massachusetts. The weight, if rightly remembered, was 64 lb. It was cut open in presence of the audience, and the usual cavity found crowded full, or nearly full, of fibre. There was cavity only large enough to hold about one quart of water, the outer surface was indented with the enormous pressure; the iron bands of the harness which rested on it being only about 1 inch wide. Could a larger part of its surface have been safely covered from the light it would, it is thought, have accomplished even more. However, it was agreed that it has given an instructive lesson of the enormous vital power in the soft cells of a pulpy vegetable, seven-eighths of whose substance is water.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Large Mushrooms.—Four Mushrooms, which I cut from our house here on the 12th inst., weighed together exactly 1 pound, and the largest of them measured 6 inches in diameter. Is not this rather an unusual size?—JOHN R. STIRLING, *Park Wern, Swansea.*

A Large Head of Cabbage.—The weight of the fine heads of field Cabbage exhibited at the Royal Dublin Society's show last week, by Mr. Bird, gardener to Lord James Butler, averaged each about 3 stones; each, too, was as solid as a block.—*Irish Farmers' Gazette.*

White or Silver Beet.—When this can be got true, it forms an excellent winter vegetable before Christmas, taking the place of Seakale; and among vegetables on the exhibition table in the autumn months, nothing—not even Celery—looks so well as this Silver Beet. Associated with Tomatoes, Carrots, and similar produce, its effect is excellent.—STAMFORDIAN.

Growing Potatoes for Exhibition.—I shall feel greatly obliged by vegetable exhibitors and Potato growers giving me the benefit of their experience on this subject. The cleanest and best-shaped Potatoes I have ever seen were grown by Mr. Frisby, at Blankney. Let us, therefore, hope that he will favour us with some account of his mode of growing them.—IGNORAMUS.

Prices of Potatoes.—I am anxious to learn the prices which Potatoes are fetching in different parts of the country, and it might be useful if, at the same time, it were mentioned whether or not disease had been prevalent. About Stamford Potatoes have gone bad after having been lifted for storing, especially where they had not been taken up as soon as they were ripe.—ESQUIRE.

Celery Fungus.—I send you some leaves of Celery suffering from a disease of some kind, which made its appearance about the end of September in different parts of the rows, in the form of small brown spots. It increased very fast, spreading all over the leaf and from plant to plant, turning them yellow; it then creeps down the plant, stopping growth, and then it begins to rot. I have taken up as many as a dozen in succession all diseased and rotten. If taken up just as they begin to look yellow, they can be used.—J. C. T. W. [Your Celery is infested with a Fungus called *Puccinia apii*.]

THE LIBRARY.

THE CULTIVATION OF ROSES IN POTS.*

ANY work throwing light upon, or likely to give a stimulus to, the cultivation of so beautiful and so useful a flower as the Rose is sure to be looked upon graciously by all lovers of garden flowers. The little book before us, although it disavows any intention of instructing professional growers, and is intended merely to furnish a guide to amateurs, is compiled with so much care by its author, and embodies the result of so much practical experience, that it cannot fail to be useful to all. That it has now reached its fourth edition is a proof that its merits have, ere this, been recognised; and its enlarged form and the conversion of what originally were brief notes into more solid matter must increase its value, and, we hope, extend its circulation. The volume is divided into two parts; the first treats of the cultivation of Roses in pots; the second is the autobiography of a pot Rose, an amusing section, from which we borrow the annexed wood-cut. The following useful remarks upon pruning we have extracted from the first portion of the work:

Pruning.

About the middle of November pruning may be performed, in order to effect an early bloom. The plants having been thinned out previously, all that is now required is the shortening-in of the remaining shoots. It is a difficult matter to lay down any precise rules with regard to pruning, upon the judicious adaptation of which depends not only the well-forming of the plant, but, in a great measure, the perfection of flowers also. In order to prune Roses with certainty of success, we ought to know the character of each plant we are about to operate on; for Roses of the same group oftentimes require very different pruning. The best criterion we can offer is, perhaps, the habit of growth. Among the Hybrid Chinese, the two favourite old Roses, Charles Lawson and Chénédolé, both vigorous growers, frequently occasion great disappointment by not blooming. The failure will probably be found to arise, in most cases, from the method of pruning. These Roses, and others of like habit, should be well thinned out, and the shoots that are left for flowering shortened but little. Others of the same group (Hybrid Chinese), that are weak or moderate growers, may be shortened in close; such as Comtesse Lacépède, a beautiful and well-known Rose. Then there are varieties of intermediate growth, which may be pruned in proportion. The groups Provence and Moss may be pruned closer than the Hybrid Chinese. The Autumnal Roses there is little fear of pruning out of bloom; early or late, they are sure to flower. The Chinese and Tea-scented, when grown on their own roots, should be cut close, to induce them to throw up shoots from beneath the ground, as these will grow much stronger than shoots formed above ground, and flower beautifully through the summer and autumn. One point, too, should be borne in mind, that Roses, when grown in pots, may be pruned closer than when grown in the open garden. One season I shortened back the shoots of the newly-potted Autumnals, Moss, and

Provence, from two to four eyes; and, what with thinning and shortening, the plants looked very naked, and, at first sight, appeared to many to have been cut too much. But considering that each of the remaining shoots would produce two, three, or four new shoots, and that the plants were not in the open ground, but in pots, it was evident such was not the case; and this their after-growth and flowering fully confirmed. When dealing with the most vigorous kinds of Hybrid Chinese and Hybrid Perpetual, I left no more than six eyes on a shoot; and though the plants were young, and, consequently small, their blooming, both as regards the size and the abundance of flowers, was all that could be wished.

FLORISTS' FLOWERS.

THE Wood Anemone is a pretty white flower, tinged with violet. This is the original of an Anemone which we shall find in another part of the garden; there, its foliage forms a beautiful rich green turf, from which spring simple rose-shaped Anemones, red, scarlet, purple, blue, violet, white—or streaked with all these various colours. A bed of these is one of the richest and most magnificent sights imaginable. The Anemone is one of the plants called florists' flowers. There are people, sober in their pleasures, who concentrate their cares upon a single flower. There are amateurs of Tulips; for them there is no other flower in the world but Tulips—other flowers are weeds; and still further, among Tulips, there is only the Tulip with the white ground, and among Tulips with the white ground, there is only the Tulip with the rounded petals. The year begins for them on the 15th of May, and finishes on the 28th of the same month. There are amateurs of Roses, there are amateurs of Auriculas, there are amateurs of Pinks, there are amateurs of Dahlias, there are amateurs of Camellias, there are amateurs of Ranunculuses, there are amateurs of Anemones: these are the only flowers—others are called bouquets: and you should see with what a tone and manner they pronounce the word bouquet! So with sportsmen, there are some animals that are game, and others that are not. Of all this race, the amateurs of Tulips are the most ferocious; not that the others, however, are remarkably mild, or that I advise anyone to approach them without due precaution. It sometimes happens that the amateurs of Anemones cultivate Ranunculuses simultaneously, but they expose themselves to be treated as dabbles

A well-grown pot Rose.

by severe amateurs. I knew a Tulip fancier, who, at the season for planting his Tulips, made every year two composts—one of maiden earth, sand, and leaf mould; the other of clay, pigeons' dung, and animal mould. In the first, which is favourable to Tulips, he planted his own roots; in the other, which combined all the contrary conditions, he placed such as he had received as presents, or in exchange. If he thinks his cares insufficient, he waters them with soap-suds. Then, at the period of their blooming, after having made you admire his own plants, he leads you to the others, and tells you, in a delightfully self-sufficient tone—"These are plants which distinguished amateurs have been kind enough to offer me in exchange for mine!" To return to Anemones. They were brought into France from the East Indies, more than two centuries ago, by a Monsieur Bachelier, who was ten years before he would give a single one to anybody. A magistrate went to see him in his robes, and purposely making their folds drag over the Anemones in seed, contrived to carry away a few of them, which adhered to the wool of his robe

* "Observations on the Cultivation of Roses in Pots; including the Autobiography of a Pot Rose." By William Paul, F.R.H.S., Author of "The Rose Garden," &c. Fourth edition. Kent & Co., 23, Paternoster Row.

Never speak to an amateur of Anemones, of anything else but his Anemones; if you say to him, "I have a beautiful Pink," he will ask you what sort of an Anemone that is. But do not imagine that the amateurs of flowers love flowers better than the learned do: the learned do not acknowledge the cultivated Anemone, they say that it is a monster, or they dry it, paste it on paper, and write barbarous words under it. Amateurs content themselves with requiring difficult conditions of Anemones; thus there is a sort of green calyx, which ought to be placed just at one-third from the flower, and two-thirds from the earth, and without this the Anemone may display the richest colours in vain—it will be dismissed from the bed, and declared nothing but bouquet! I spare you a dozen more or less singular conditions which are required of these poor flowers. Here is a Peony, a sort of gigantic Rose, of the most beautiful red. There are no amateurs of Peonies, unless it be the tree Peony, because that is perhaps less beautiful, more difficult to cultivate, but more scarce. The ordinary Peony, red, rose-coloured, or white, is held in no esteem. But it is so common! Thanks, O Lord, for all that thou has created common! thanks for the blue heavens, the sun, the stars, murmuring waters, and the shade of embowering Oaks—thanks for the Corn-flowers of the fields and the Gilly-flowers of the walls—thanks for the songs of the linnet and the hymns of the nightingale—thanks for the perfumes of the air and the sighing of the winds among the trees—thanks for the magnificent clouds gilded by the sun at its setting and rising—thanks for love, the most common sentiment of all—thanks for all the beautiful things thy stupendous bounty has made common! The Peony was formerly, however, much celebrated: it drove away tempests, broke enchantments, defeated witchcraft, and now and then cured epilepsy. Its name, *Paeonia*, came from Paeon, a celebrated physician, who employed it to cure Plato, when wounded by Hercules. The root of the Peony, therefore, was not taken lightly; it was at a certain hour of the night, and during a certain phase of the moon; and still further, it was necessary to take care not to be observed by the woodpecker, whilst digging it; whoever was observed by the woodpecker became blind. The Peony is no longer anything but a beautiful and splendid flower, despised by amateurs, and seldom seen but in poor gardens.

ALPHONSE KARR.

FOREIGN FRUITS IN COVENT GARDEN.

The importation of foreign fruits to this country is destined at no distant date to influence to a considerable extent the market value of home-grown produce. Indeed, such imports as now find their way to Covent Garden alone, form no inconsiderable proportion of the gross supply of the market. The fact is, we are not a fruit-growing people, and on that account the demand for that kind of produce is greater than the home-grown supply; hence, recourse to foreign sources has been had as the only means of enabling dealers to satisfy the demands made upon them; and the plan, adopted in the beginning to meet an emergency in one or two special cases (early Strawberries, for example), has now become universal, and is productive of excellent results. Whatever tends to cheapen fruit and to bring it within the reach of the masses, is deserving of support, and this the foreign trade has already done. Grapes, Melons, Pines, and other fruits of warmer latitudes than our own have been brought within the reach of every artisan who cares to eat them, and the probability is that ere long imported fruit will be still cheaper. It is scarcely likely that the health of the public will be worse in consequence of this, for physiologists tell us that good fruit is the best food that can be eaten at any season, and one cannot but believe that a cluster of luscious Grapes or a good Pear is at least as likely to quench thirst, under a broiling sun, as the questionable beverages usually consumed on a summer's day with that intention. Although we are a nation of beef-eaters by birth yet a taste for fruit is rapidly extending amongst all classes, and the proof of this is that our home-grown supplies are insufficient to meet our demands. Just at the present time Oranges are coming in very largely and are selling at remarkably low rates. These are imported from St. Michael, Lisbon, Valencia, Messina, and Palermo. Lemons are also very plentiful, and come principally from Malaga, Messina, Palermo, and Alexandria, packed in long flat or round-topped cases of lath or thin boards, the packing material consisting of Indian corn or Maize husks. The first importations generally arrive about September or October, and are characterised by their acidity, pale colour

and small size. Later on in the season finer and better ripened fruit makes its appearance; but, notwithstanding the present expedition in transport, we seldom obtain fruit with that luscious and agreeably perfumed flavour that distinguishes Lemons when plucked ripe and eaten off the tree. Like all other cultivated fruits the Orange (*Citrus Aurantium*) sports into numerous varieties; indeed, this must have occurred to all who buy the fruit in this country. The differences chiefly consist in size, colour of rind or flesh, thickness of the skin or rind, sweetness, and time of ripening. Among the excellencies of the Orange, as an imported fruit, are its keeping qualities; indeed, it is a fruit nearly always cheap, and readily obtainable almost all the year round. Apart from those eaten as imported, many thousands of cases are annually manufactured into marmalade and also into wine. The best marmalade is that prepared from rind of the Bitter or Seville Orange; but fruits of all sorts are used for the commoner and cheaper preparations of this agreeable conserve. Among the many distinct varieties brought to Covent Garden are the following:—The Blood Orange; this, in external appearance, resembles the common St. Michael's; but the pulp is of a deep crimson tint, and not yellow as in ordinary kinds. The little Tangierine is deservedly popular, its flavour being most delicious. It is readily known by its small size, and flattened or oblate form, while its skin or rind is very brittle and delicately perfumed. Citrons are oblong or rounded, with a remarkably rough skin; indeed, in general appearance, they most resemble gigantic Lemons. The Shaddock (Forbidden Fruit) and Pomeloes are large, and highly ornamental, forms of Citron, and of little use except for conserves or marmalade. Among the rarer forms of the Citrus family we may mention the pretty little egg-shaped Chinese Orange (*Citrus japonica*), home-grown fruit of which makes its appearance at rare intervals. This variety is characterised by its

Pine as imported from St. Michael.

bitter pulp and sweet lightly-perfumed rind, the latter being of extraordinary thickness as compared with the size of the fruit. Under the name of "Kumquats" or "Counquats," this fruit is now commonly imported in a preserved state, and large jars of it may be purchased at about six or seven shillings each, or at about a shilling per pound retail. The Orange is, perhaps, the oldest of our imported fruits, and imports of it of late years have increased with great rapidity. Pines are now largely imported from St. Michael and the West Indian Islands, the varieties being the same as those grown by us at home, and the fruit equally fine, both in appearance and flavour. Their introduction in large quantities, and consequent cheapness, will do much towards checking Pine culture in this country, especially as it is generally a very costly undertaking. The St. Michael's Pines are great favourites with the dealers, on account of their being invariably sound at the core or heart; and, in this respect, they are more to be relied on than fruit grown at home. The plan of culture adopted at St. Michael is pretty much the same as that at home, only that the sun takes the place of our costly heating apparatus, and the expense of fuel is also got rid of at the same time. The mode of packing the fruit is peculiar and deserving of notice, and our illustration shows how this is effected at a glance. A round, square, semi-circular, polygonal, or triangular case is made by tacking laths on to the variously-formed ends, as here shown. A piece of board, the same shape as the end, forms a rest for the base of the fruit, and the stem protrudes below, where it rests in a common flower-pot filled with moist Moss or bark. The crown above is securely held in its place by two pieces of board, which fit round it at the base, just above the fruit, and are secured by tacks driven through the upright laths all round the circumference. These cases, each holding a separate fruit, are then packed in large crates; and, by these simple contrivances, ample ventilation is secured, and each fruit sets firmly in its place, so that all danger of bruising, by contact with each

other or any foreign substance, is avoided. This plan is worth the attention of growers at home who have to send fruit to a distance. Amongst the most important of all the recently imported fruits, however, are Grapes, a fruit long restricted to the tables of the wealthier classes; but excellent Grapes may now be purchased in Covent Garden, from August to January or February, at prices varying from sixpence to one shilling per pound. Grapes are imported from Holland, Spain, Portugal, Germany, France, and the Channel Islands. The best kinds are the Dutch and German or Hamburgh Grapes, which arrive about October in considerable abundance. These are equal to home-grown fruit in appearance, and are much lower in price—the average prices ranging from ninepence to one shilling per pound. The flavour is not so good as that of home-grown fruit, but by some they are liked even better, on account of their pleasant acidity. These Grapes come packed in round baskets or hampers (as shown in our illustration), each containing from 10 to 15 lbs., and in a plentiful season these baskets may be bought from seven to ten shillings each. The most noticeable feature in connection with these is the system of packing adopted by the growers. No packing material of any kind is used, the fruit being carefully gathered during dry sunny weather, and placed at once in these baskets, which are gently shaken and filled, so that the cover, when fastened down securely, presses firmly on the fruit. We have seen fruit packed in this manner turned out as fresh here in the London markets as if just gathered; and the hint is well worth general application by gardeners when packing fruit of home growth, for it is a noticeable fact that much of the fruit sent to Covent Garden by Grape growers in England is completely spoiled

Basket in which Grapes are imported.

in appearance through being swaddled in cotton-wool or paper, whereas, if pressed firmly in baskets or cases, but little of the bloom is lost. The delicious little amber-berried Chasselas de Fontainebleau (Royal Muscadine), so common in the fruit markets of Paris, is, unfortunately, but rarely seen in Covent Garden. These are packed tightly in small oblong boxes, and bear carriage well, but the retail dealers do not care for them, because they do not keep well, and must, consequently, be sold on arrival for just whatever they will fetch. These Grapes are sold from sevenpence to twopenny per kilo (about 2 lbs. English) in the French markets, or even cheaper by the box of eight or ten pounds. Within the last few years a kind of Muscadine, very similar to the Royal Muscadine in appearance, has been imported from Lisbon and other parts of both Portugal and Spain. These are very sweet and juicy, and keep for several weeks without injury. They are imported in boxes, and sell at prices varying from fourpence to one shilling per pound retail, and much cheaper by the box or at auction sales. In size and flavour these are fully equal, and in many cases superior, to Muscadines of home growth. These come in before the Hamburghs, or "Grocers' Grapes," as they are called by the trade, and last until the Almerian fruit arrives in November. A large red or purple-skinned Grape is imported in limited quantities from Lisbon, and is of excellent quality, the flesh being firm and juicy. It keeps well, but the berries fall from the stalks, which are very brittle as with "Aramon," a French wine Grape which it in some respects resembles. The White Almerian Grape carries on the supply from November until March or even later, but it is a thick-skinned and insipid-flavoured variety, with nothing but its long-keeping qualification to recommend it. This Grape is known in some English collections as "Bowker," but is not worth room in a house, being of a coarse habit in every respect. It is, however, worth a trial as a stock for the late-keeping kinds, as White Lady

Downes, Mrs. Pince, Black Muscat, and others. Foreign Peaches are rather limited in supply, but during the last year or two a few excellent samples have been sent by the Montreuil growers in very fine condition. The excellence of the French Peaches is well known, and, as well-packed cases may be despatched from Paris at 4 o'clock p.m. and arrive in London by 10 or 12 a.m. the following morning, there is no reason why this luscious fruit should not be largely sent to us by French growers. During the past year a few samples of yellow-fleshed Peaches have arrived from America, but these are of second-rate quality, and much cannot be expected of this most delicate of all fruits after a ten or twelve days' voyage, and the not over-careful handling to which it is subjected. We must look to France and the Channel Islands for any additional supply of Peaches, as the climate and transport arrangements are well nigh perfect for all the purposes of culture and importation. A few Nectarines also come from France, generally packed in small deal boxes, and these sell at from 2s. to 3s. the box. Green or fresh Figs are more plentiful than formerly, the principal source of supply being the celebrated old Fig orchards at Worthing (Sussex), and considerable quantities also come from Guernsey, and a few from Jersey. The supply of these is also supplemented by a few choice samples grown in our hot-houses at home, these, as a rule, being the best-flavoured fruit. Melons come from Lisbon, Cadiz, and from many of the ports of the Mediterranean—the Cadiz or green-flesh Melon being often of very excellent quality, notwithstanding that the fruit must necessarily be gathered and packed before it attains that precise period of luscious ripeness which renders it so acceptable in most tropical and sub-tropical climates. The true Water Melon is rarely seen in our markets, although it is common enough in the ports of the Mediterranean, and bears carriage well. This is larger than the Cadiz Melon, and of a fresher green colour outside, while the crystalline, melting flesh is of a delicate rose or salmon colour, and in this the jet-black seeds are firmly imbedded. In hot weather this is a delicious fruit, and we should like to see it imported more largely than is now the case. The small brown densely netted Musk Melon occasionally makes its appearance, but the main demand is still supplied by Portuguese and home-grown fruit. Apples are now largely imported from America, the Newtown Pippin being an especial favourite here. These are packed in barrels, each holding from two to three bushels. No packing materials are used, but the lid is pressed down tightly, and this securely protects the fruit from friction. Pears come principally from France, the Channel Islands, and from Germany and Holland; the favourite varieties are Jargonelle, William's Bon Chrétien, Marie Louise, Duchesse d'Angoulême, Beurré Clairgeau, Louise Bonne of Jersey, and two or three other well-known standard varieties. These come packed securely in wooden cases, and suffer very little in transit. The enormous specimens of Beurré Clairgeau and Belle Angevine (Uvedale's St. Germain's), so often seen exhibited at fancy prices in our fruiterers' windows, come from Jersey and Guernsey, and, apart from their monstrous size and high colour, have little to recommend them. Among the rarer fruits which are from time to time imported to Covent Garden, we may instance Prickly Pears, the fruit of a Cactus (*Opuntia vulgaris* and other species); Pomegranates, the pulp of which is delicious eaten with port wine and sugar; West Indian Custard Apples, the fruit of *Anona squamosa* and *A. reticulata*. Bananas are largely introduced from the West Indian Islands, some of the clusters weighing seventy and eighty pounds each. When thoroughly ripe, the flavour of the best kinds of Bananas is simply delicious, but this is before it is ripe. The fruit is produced by *Musa Cavendishii* deteriorated in imported fruit, as it has to be cut from the plant and *M. sapientum*, both of which are largely cultivated in most tropical countries and used as common articles of food by the natives. Litchis are now brought from China, and are sold here at from three to four shillings per pound. These are the fruit of *Nephelium Litchi*, one of the most popular of all imported fruits, not even excepting the Apricot. The round variety is most common, and has a thin shell of a reddish-brown colour, covered with rough warts. The pulp, when fresh, is sweet and jelly-like; but, as imported in a dried state, it may be likened to that of French dried Plums or Prunes;

one of the most peculiar characteristics of this fruit is its extreme lightness. The Loquat, or Japanese Medlar, another Chinese and Japanese fruit, is sometimes imported. This fruit is produced by *Eriobotrya japonica*, a small evergreen tree, sometimes grown as a foliage shrub in this country. The fruit is borne in clusters, each being about the size of a pigeon's egg, and of a delicate yellow colour, suffused with rose when fully ripe, and possessing a delicate and agreeable sub-acid flavour. American Peanuts, as the

fruit-pods of *Arachis hypogynæ* are called, are far from uncommon, and are easily known by the two seeded pods being beautifully netted, so that they resemble little wicker baskets. This plant is a native of the Cape, but is now widely distributed in most tropical and inter-tropical countries. A striking peculiarity possessed by this plant is, that after flowering, the peduncles bend down and thrust the young fruit into the soil to ripen—hence one of the essential conditions necessary to its growth is a light open soil. These nuts, slightly roasted, are sold in American theatres as extensively as Oranges are in London. A valuable oil is also extracted from them in considerable quantities. Brazil Nuts and Sapucaia Nuts are both produced by species of *Beccythis*, natives of the forests of Guiana and Brazil. The last named are by far the best in quality and are principally imported from Para. The so-called nuts, when growing, are enclosed in urn-shaped receptacles, popularly known as "monkey pots," these are, however, seldom imported, the nuts being

taken out and packed in bags and boxes for shipment. Cocoa Nuts come in considerable quantities from the West Indian Islands and other parts of the tropics, throughout which the Cocoa Nut Palm (*Cocos nucifera*) is grown as one of the most valuable of all vegetable products. In their original state the nuts are covered with a thick triangular covering of fibrous and cellular matter, that bears some analogy to the husk of a Walnut, but this is stripped off to lessen their bulk previous to their being packed for shipment. F. W. B.

TREES AND ARCHITECTURE.

THE interesting paper read before the Architectural Association, and published in THE GARDEN (see p. 548), is well worthy the careful study of horticulturists. In that paper will be found many interesting passages from the works of both architects and landscape gardeners; but the deductions sometimes arrived at from the discussion of the merits of such passages too often tend to show that an architect cannot possibly be competent to settle matters which belong exclu-

sively to a profession requiring fully as much training as his own, and of a very distinctive kind. It is well put by the author, that a distinguished philosopher, when pretending to settle points of an artistic character in regard to architecture and landscape, is certain to fall into errors, which one practically and suitably trained could not possibly commit. Mr. Herbert Spencer is the philosopher alluded to, who says "that regular architecture cannot, by any possibility, be suited to an irregular site," and that "any picture representing such a combination must be essentially unpicturesque." Both experience and theory have, however, long ago proved that the placing of a regular building in the midst of a rugged and irregular scene imparts additional value to the building. The accomplished Cockerell tells us in his picturesque way, that, in the case of temples so situated, the rugged scenery formed "a powerful contrast with the highly-finished object towards which the steps of the devotee were directed;" and it may be asserted, with equal force, that Gothic

Painted Trees and Harmonized Architecture.

architecture is fully as effective as Greek in such a situation; as is evidenced in the picturesque pile of Mont St. Michael, and on a smaller scale in St. Michael's Mount, Cornwall, both examples tending to illustrate the evident fact that either rocks or trees, by the irregularity of their forms, heighten the effect of buildings. Much that is vague and contradictory occurs in the well-arranged and well-written paper alluded to, both in the original matter and in the interesting and eloquent, though often misleading, quotations from authors who have

written on the subject; but, instead of a captious analysis of passages, which are useless from their vagueness and want of definition, or from erroneous views concerning the use of trees according to their forms, it will be better to put forward a few remarks from the horticulturist's, rather than the architect's, point of view, in regard to the production of beautiful sites for buildings, or the improvement of naturally fine situations by judicious planting. Repton, seeking some kind of fixed principle by means of which he could readily adopt the character of his plantations to the buildings for which they were destined to form the surrounding scenery, arrived at the conclusion—very sound in the main—that trees, which rise, steeple-like, to a point, like the Cypress, the Poplar, and many others that might be named, are well suited to associate strikingly and pleasingly with architecture in which horizontal lines chiefly prevail, such as those presented by Greek temples, or, what is more to the purpose in the modern practice of landscape gardening, the Palladian manner, as exhibited by many of the palaces and villas of Italy. As a general principle, Repton's view is, doubtless, a sound one; but then he wrote at a time when more than half the noble kinds of trees, now available for the purposes of the landscape gardener, had not been introduced, and, had he lived in the present day he might, doubtless, have modified the arbitrary and sweeping character of the hard and fast lines to which he then adhered. Our illustrations, entitled, respectively, "Pointed trees and horizontal architecture," and "Round-headed trees and horizontal architecture," will serve to exemplify how far the Repton principle was correct in the main, and how far it was insufficient, and ought not to be arbitrarily considered an invariable rule. In the first example the prevailing horizontal lines of the balustraded terrace wall of an Italian villa, which are only slightly broken up by statuary and vases, have certainly, at a glance, a very agreeable aspect, backed as they are by the dark vertical forms of the aspiring Cypresses. The square-topped wings of the villa,

with its arcades, rising above the arch of the bridge, also afford a charming contrast to the strong vertical line furnished by the trunk of the Stone Pine, and the irregular character of the ramifications, which form its crown, greatly assist the effect. In the case of the Pine trunk, it is, however, almost as much the irregularity of the line as its direction, that renders the effect so pleasing; and, while speaking of the vertical character of the Cypresses in contrast with the terrace wall, we have not sufficiently considered that it is the perpendicular character of the fountain, above and below the balustrading, that forms the true opposition of lines in that part of the composition; so much so, that the combinations would be absolutely improved were the high jet of the fountain backed by round-topped, instead of pointed trees. It will also be seen that the irregularities of the foliage in the foreground, passing boldly athwart the irregular lines and finished details of the architect's work, greatly aid the pleasing character of the general composition. Our second illustration serves to prove that a striking opposition of lines is by no means absolutely necessary in order to form an agreeable composition of architecture and foliage. The chief feature of the second picture, consists of a structure, in the manner of the French "revival," which serves as the frame-work of a fountain; and its main lines, as in the style of the Italian revival, led by Palladio, are horizontal. Therefore, upon the crude theory that no foliage, but such as exhibits a vertical character of growth, would group with it pictorially, it

Round-headed Trees and Horizontal Architecture.

would require to be surrounded with Poplars and Cypresses, as a matter of course. Yet, it is conclusively shown in our illustration, that the round-topped tree in the foreground—a Horse Chestnut, with spreading branches—groups admirably well with the horizontal lines of the architecture; while an Acacia, beyond, although its general form is composed of somewhat horizontal stages of foliage one above another, groups equally well with the architectural features of the composition. In fact, with taste, judgment, and, above all, a

thorough knowledge of the vastly extended arboretum which we have now the privilege of making use of, trees and architecture may be combined in an endless variety of ways, all equally beautiful.

H. N. H.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

WHERE it is the intention to plant or remove Gooseberries and Currants, the sooner such work is done now the better, if the weather be mild; but do not plant anything when the ground is crusted with frost, as in the operation the frozen soil gets in contact with the roots, which is by no means calculated to benefit them; the ground should be well dug before it is planted, even if it has been under vegetable crops before. These fruits (except Black Currants, which like shade) are best grown on good open ground; they will, however, succeed betwixt Apple and Pear trees, if the latter are not planted too closely. In such situations they frequently bear well when the crop in more open places gets cut off by spring frosts; the ground round these, and any trees that are newly planted, should be mulched as far as their roots extend with half-rotten manure. Raspberries should also be planted; for this fruit the ground should be well enriched by digging into it a good dressing of manure previous to planting; existing plantations of this fruit should be pruned and tied, and, where stakes are used, renewing such as are decayed; few crops require, or will better pay for, a liberal use of manure than Raspberries. Even old plantations of them that have become weak, can frequently be brought round by enriching the ground, and otherwise bestowing on them judicious cultivation. One of the principal things to be observed in the case of the Raspberry, is never to use a spade amongst them; the greater portion of the roots lie near the surface, and if the spade is employed in digging, quantities of them necessarily get injured; even fork-culture should not be too deep. Strawberries should now be cleared of runners and the ground should be slightly forked over; these, like Raspberries, are surface-rooters, and should never have the spade used among them. If the beds are getting old, and the ground poor, a dressing of manure may be forked in.

Pruning Gooseberries and Currants.—Remove each year a portion of the old wood, and leave in its place new shoots. Young or small bushes, which it is desirable should grow larger, should merely have surplus wood removed, and the points shortened of such as is to remain. The buds of this fruit are liable to be attacked by birds after the commencement of the new year; they should, therefore, be protected, either by rendering them unpalatable, or by scaring away the marauders. This latter is more effective, as regards sparrows, than in the case of bullfinches or titmice. As a deterrent, there is nothing so effectual as threading the trees over, after they have been pruned, with white cotton. This should not be too thin, or it is not sufficiently visible to effect what is required, especially when it has become a little discoloured by exposure to the weather; the best material is that which is spun for common dip candle-wicks, unravelled, using a single strand, and threading it not too tightly, but leaving it so that it will move a little with the wind; thread it a dozen times across each tree; and, so far as sparrows are concerned, I never knew it to fail. To render the buds unpalatable, take some unslaked lime, and boil it as you would for making lime-wash; then add as much water as will make it thin enough to be applied to the trees with a syringe, using a coarse rose. In mixing it, as much soot should be added as will make the dressing a dark brown colour; choose a day that is likely to be such as will ensure the dressing getting quite dry, for if much rain falls before it gets dry, it will, in a great measure, be washed off. In pruning Red and White Currants, if the trees are as large as required, all the current season's growth may be cut away, except any strong shoots that spring from the base of the plants, which it may be desirable to retain in place of some of the old wood; these, after pruning, should either receive a dressing with the lime and soot mixture, or have the thread wound over them; neither must this operation be delayed, for, if once these feathered delinquents commence their attacks, in a very few days they will not only spoil the coming season's crop, but also destroy the bloom spurs that should last for years. Black Currants are not subject to such attacks, neither do they require so much use of the knife, except for keeping the bushes sufficiently open. After the pruning is completed, gather up all the strongest shoots of Apples, Pears, and Currants, and tie them in small bundles; they will be found useful for supporting flower-stems of such things as Pinks, and other small-growing plants. When all the ground amongst the bush fruits is cleared of the prunings, put on such manure as may be required, and fork it in without injuring the roots. The greatest enemy to the Gooseberry

is the caterpillar, which each season makes its appearance more or less where it has been in quantity the previous summer; unless completely destroyed, it is almost certain to appear again the succeeding season, for, if the caterpillars have been allowed to remain unmolested after having run their course upon the trees, they will, in the autumn, assume the cocoon state, and bury themselves in the soil near the stems of the bushes, remaining there until the sun's warmth completes the development of the perfect-winged insect, which will afterwards deposit its eggs on the leaves, where they quickly come to life, repeating the work of destruction entered on by the generations which preceded them. The most effectual method of dealing with these pests, and also that which entails the least trouble, is to destroy them when in the ground in the dormant state. This can be done by spreading about half a spadeful of dry lime over the soil, so as to let it extend 8 or 10 inches from the collar of the tree in each direction. This should be put on after the ground has been dug, and allowed to remain through the winter, when its caustic properties will destroy the embryo. Seasonable attention in this matter will save a good deal of after trouble, and the lime will benefit most soils. As to varieties of bush fruit, it is a mistake, for ordinary purposes, to grow too many. The following are useful kinds:—*Gooseberries (Red)*—Crown Bob, Red Warrington, and Keen's Seedling; (*Yellow*)—Yellow Warrington and Glory of Ratcliff; (*Green*)—Green Gascoigne and Heart of Oak; (*White*)—White Champagne and White-smith. These nine sorts will not disappoint anyone who may plant them. *Currants (Red)*—Cherry, Long-bunched Red, or Wilmots; (*Black*)—Black Naples and Lee's Prolific; these and the White Dutch are enough for general cultivation. *Raspberries (Red)*—Red Antwerp, Barnet, and Rivers' Large Monthly. (*Yellow*)—Yellow Antwerp. As to varieties of Strawberries it is difficult to advise, for the kinds that will succeed in one locality are useless in others. For an early crop there is nothing yet that has surpassed Keen's Seedling; it is not quite so early as Black Prince, but the fruit is much larger and is very fine in flavour. President, Sir C. Napier, and Sir Harry, are good free-bearing sorts that will succeed in most soils where Strawberries will do at all. There is yet nothing for excellence of flavour and beauty of fruit equal to British Queen, where it will succeed, but it requires a good strong soil, which all varieties of this fruit delight in; but which is more essential for the successful growth of this sort than of most others. In the kitchen garden, if there is an appearance of severe frost, provision should be made for the protection of such crops as are liable to be injured by it. The tender condition of most plants in the south of the kingdom is consequent upon the more than usually late growth of the present autumn, induced by copious rains after protracted drought; and the prolonged summer that we have experienced has left most things in a condition very liable to be injured.

Protecting Celery.—Care should be taken that Celery is not subjected to much frost, or it will not keep so long, however firm and solid the variety may be; for covering material, use Pea haulm, which, if put under cover when pulled up and kept dry until required, is very useful for such protecting purposes; if in a neighbourhood where it is plentiful, the common Brake is a good material, if not, stable litter may be used; but whatever is employed will be found much more effectual if not in absolute contact with the tops of the Celery. To prevent this, take some stout pieces of old Pea sticks and push them down in the rows betwixt the plants, then take some of the longest and straightest of the Pea sticks, or such as have been used for Runner Beans, and tie them lengthways to the upright sticks, a few inches above the tops of the Celery; on these place the litter or other material, letting it hang well over the sides like thatch; this will be the best way of protecting it from frost, and costs little more in additional labour than simply placing the material upon the tops of the Celery. Winter and spring Broccoli is frequently saved from being killed in severe frosts by the slight protection afforded by laying old Pea sticks down moderately close upon them, as these break the full force of the cutting frosty wind. During severe frosts, or when there is appearance of snow, cover Parsley with shutters or boards, if no frames are at hand, not allowing the covering material to absolutely touch it. Standard Roses, that have been several years planted without removal, if they throw up many suckers, should, if not done earlier in the season, be taken up, and have all their suckers well trimmed off, adding, if necessary, some new soil and manure. In an amateur's garden, where there happens to be not more than one glass-house, it frequently has to do duty for a number of things, comprising a variety of plants on the stages and shelves, with Vines overhead. Undoubtedly it is much better for the latter to have a house to themselves, for where both are grown together, it must necessarily entail a compromise of treatment; neither the plants or the Vines, get exactly what they require, yet, under such circumstances I would

by no means discourage the attempt in growing some Grapes over the plants (and I know amateurs who succeed very fairly with both), provided too much is not attempted with either, but not so as to shade the latter too much, which will be the case if the number of Vines are planted that is usual where the house is devoted to the cultivation of Grapes alone. Where a house is made to answer this double purpose, it should be span-roofed, as light as possible, and one or a couple of Vines should be planted at one end, and run lengthways under, or a little way from both sides of, the ridge; by this means they get a good deal of length for extension—one great essential in Grape culture—and they do not so seriously interfere with the plants grown underneath. The sorts should be such as are of easy culture, as Black Hamburgh, and if a white variety is required nothing will be more suitable than the White Mascadine.

GARDENING FOR THE WEEK.

Roses.

POT ROSES placed in the forcing house in the beginning of November will now be coming into bloom; in syringing, care should, therefore, be taken not to wet the blossoms, as that would cause the outside petals to damp off, and thereby impair the beauty of the Rose. On fine sunny days give plenty of air, which not only strengthens the wood but improves the flowers as regards substance of petal, a circumstance which enables the blooms to last longer when cut than they otherwise would do. Maintain a steady bottom-heat, which Roses enjoy more than most plants. Any check experienced in this respect is apt to be productive of small and deformed flowers. A little manure-water, now and then, may be given with advantage. Sheep droppings and soot—say half a bushel of soot and one bushel of sheep droppings, put in a tub of water, make a good manure for Roses; but it must not be used too strong. Put a little of it in each can of water when watering the plants. Stauden's manure dusted over the surface of each pot, and watered in, will also be found useful. In no case, however, use manure-water until the Rose tree has fairly broken into leaf, for, if used when the plants are first placed under forcing conditions, the top buds will grow away strongly and rob the lower ones of support, in many cases spoiling the plant. Introduce plants to keep up a succession of bloom. If painted over with Gishurst, or a mixture of soft-soap and sulphur, mildew will not be troublesome.—H. G.

The Flower Garden and Pleasure Grounds.

A season of comparative inactivity may be said to have now intervened as regards these departments. The present month has been much colder than is usually the case, and the soil is generally either frost-bound or hidden by its winter mantle of snow, which not infrequently adheres to the foliage and branches of evergreen trees and shrubs until its great weight proves seriously injurious to them, by splintering and breaking off boughs, &c. To prevent this, as far as possible, it is advisable, as soon as possible after a heavy fall of snow, to attend to belts and plantations of choice shrubs, Coniferous trees, &c., and, by gently shaking them, remove the bulk of this accumulation, carefully avoiding, at the same time, injury to the foliage or bark of the plants. After falls of snow a portion of the central parts of walks and drives should be swept to render the necessary traffic as agreeable as may be; and this should always be done as soon after the snow has fallen as possible, so that the position of the walk or drive may at once be indicated, and dwarf shrubs, herbaceous plants, and edgings of dwarf Box or Grass, thus saved from serious injury by being trampled on. Choice Carnations, Anemones, and other Alpine plants, should now be all safe in well-covered pits or frames; while the tubers of Dahlias and bulbs of Gladioli, &c., should be stored in convenient places beyond the reach of frost; and this should also be carefully excluded from structures containing bedding plants, which should always, if well rooted, be kept as cool and quiet as possible, as it is by no means advisable to encourage growth in the absence of light and air. Nothing, however, is so inimical to bedding plants at the present season as damp; every possible care, therefore, must be taken to prevent, as far as this can be done, drip from the roofs of such houses or pits which may contain them. All dead and decaying leaves, &c., must be removed whenever necessary, and every opportunity taken which the state of the weather may afford to admit fresh air, to render the plants as hardy as possible. Should milder weather make its appearance, let store pots of such plants as the Verbena be at once well dusted with flowers of sulphur. There may also be found leisure now to take a rough estimate of the stock on hand of the various kinds of plants required for the ensuing season, and this should be compared with the list of requirements, which should have been made during the last summer or autumn; and

whenever a deficiency is shown, preparation for increasing such varieties should be made early during the ensuing year. But little, if any, advantage is likely to be gained by attempting to propagate bedding plants during the dull dark days of mid-winter. During dry or frosty weather, got, as soon as possible, a fertilising compost prepared, ready to be applied to the flower-beds and borders as soon as the spring flowering plants and bulbs are removed. It is necessary to enrich as much as possible the soil of such beds, to enable them to successfully produce two crops during each season; and it should also be borne in mind that many kinds of summer-bedding plants are exceedingly gross feeders. This compost should be frequently turned during frosty weather; frost is of itself a powerful fertiliser, and fresh surfaces can hardly be too frequently exposed to its action.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Indoor Plant Department.

Ferns.—These being in a great measure at rest, and their growth matured, they are now in a condition to better withstand the effects of repeated fumigations and extra applications of the sponge, to destroy and remove their two greatest enemies, thrips and scale, than when they are in active growth. The house should therefore be fumigated three or four times, at an interval of ten or twelve days. The plants will, at this season, too, bear stronger applications of tobacco fumes than could with safety be used during their season of growth. Go carefully, and as frequently as time can be spared, with sponge and soft brush over every plant infested with scale. Cut away such fronds as are dead, but do not remove any that have even partial life in them, as it weakens the plants. In the case of vigorous-growing tree Ferns that are outstripping the space that can be afforded them, a removal of the portion of their oldest fronds whilst in full life will be found the best means of reducing their future growth within the desired limits. Any valuable kinds that it is desirable to increase and that are furnished with ripe spores, may now have such sown in shallow pans, three-parts filled with drainage; over that put a mixture of peat, broken charcoal, and small pieces of sandstone, pressing all moderately firm; water well to close up the interstices, and to prevent the spores getting too deep; after that the spores should be scattered upon the surface; then place the seed-pans in feeders two sizes larger than themselves, and keep them filled with water so as to avoid the necessity of directly watering the spores overhead.

Indoor Fruit Department.

Vines in pots, which were placed in heat in October, will now be growing rapidly, and more water will be needed as the foliage develops. Pinch the shoots two joints beyond the bunch; do not let the shoot run to a great length and then take it off at that distance, but stop it as soon as it has formed two leaves beyond the bunch, when no check will be given to the Vine or large wound made on the tender young wood. The temperature at night should be kept about 70° when these are in bloom, and be allowed to rise to 80° with sun-heat throughout the day. Shake each bunch as it comes into bloom; this distributes the pollen, and ensures a more equal and abundant set of fruit. This is not necessary with every variety in the summer time, but at this dull season, when there is no free circulation of air in the house, it is required; no manure-water should be given until the fruit is set. Where very strong firing has to be applied, and the Vine leaves are close to the hot pipes, red spiders will be very liable to appear. The parts affected should be well syringed with clean water, and if these should be limited to one Vine or a few leaves, the most certain way of dealing with them is to give them a careful sponging. If plenty of clean water is applied in time to this pest, its eradication is not difficult. Vines do not break into growth at one time. A houseful of well-ripened canes here would be a fortnight or three weeks earlier in growth than a houseful of other imperfectly ripened ones elsewhere; so that their own judgment must be the guide of many in regulating the temperature of permanently-planted Vineries. It is not judicious to exceed 60° with fire-heat until the young shoots are from 8 to 12 inches long. After that length is attained, the heat may range from 60° to 70° when they are in bloom. Clip out all decayed berries, as soon as they appear, from Grapes which are being kept. Those bottled, as well as those hanging, will keep perfectly in a temperature 2° above the freezing point in frosty weather.

Pines.—Excepting those started for fruiting, Pines must not be kept in too high a temperature at present. During a very sharp night it is better to let the thermometer fall to 45°, or even 40°, than keep up a roasting heat of 65° or 70°. Pines will winter with advantage in a much cooler atmosphere than is generally supposed. Watering must be carried on very carefully now; suckers and successful plants require the least, and will often go for months at this season without any. Those in fruit need it often, when manure-

water is beneficial to them. Started Queens should be watered with weak guano water, after the first watering, as young greedy roots will now be forming. Any plant, which may happen to be under a drip, should be removed, or the centre will ultimately rot out of it. Plants just showing fruit should be fully exposed to all the light and sun-heat available, or they yield reluctantly from the socket. Those in bloom, or about to bloom, should be at the hottest end of the house.—J. MUIR.

Hardy Fruit.

Next to root-pruning, mulching is one of the most important operations within the entire range of fruit culture. Cultivators, seeing the tops of their trees at rest in winter, have too readily taken it for granted that the roots have been in the same state. Hence, their utter neglect and hard treatment during the severity of the winter season. Supposed to be dormant—in a state of syncope, or suspended animation—what mattered it how cold or soddened the roots were? It mattered everything. Nature took pains to render the roots of plants frost-proof; Man has taken pains to let the frost get to them. There are few more efficient frost-resisters than leaves. When these become practically dry, hardly any degree of cold can pierce through them. These are Nature's root-protectors; left where they fall, they, and the overshadowing tops of trees, are sufficient to keep the frost from the roots. But cultivators, in their wisdom, display the heads of their trees on walls and their roots within a few inches of the surface of unclotted borders. Every leaf is raked or swept up as unsightly litter—as if the cold bare soil was not cold enough for the roots, we must needs lift them much nearer to the cold air and give them a much thinner coating of soil than ever Nature designed for them. Unavoidable results follow; the frost pierces into and through the roots, and not only paralyses growth but often ruptures tissues. Even the roots of hardy trees are only hardy under natural conditions. Disturb these conditions in one way, and it may become necessary to assist Nature in all. Nature mulches her roots with leaves; we must do likewise with something that will resist the cold with equal or greater effect. Our root-coverings should be thicker and more impenetrable than Nature's, inasmuch as we have brought the roots closer to the cold. Very fleet planting is not all gain, either in winter or summer. One of its penalties is the need of a thicker mulching at both seasons. As a rule, it may be stated that fruit-tree roots should never be frozen through; assuredly, neither Peaches, Apricots, Nectarines, nor Vines should. They are always growing, and perhaps it is in the winter chiefly that they extend into new regions and take possession of fresh feeding grounds. It is difficult on any other hypothesis to account for the extraordinary activity of root-growth from the end of October to February. But little, if any fluid is needed by the tops of deciduous trees during that period. Yet the roots will run fast and multiply to an extraordinary extent. Let the frost lay hold of them a few times and growth is arrested, extension checked, and possibly the roots of the next season obliged to feed, perforce, from the empty larder of the year before. Mulch the roots to exclude frost, and they will find new stores of food and fresh supplies for the demands of the new growing season. As to the changing of the tops of trees, also, our artificial arrangements, bring the work more upon ourselves. By shelter, supports, &c., we prevent the elements, by their action, from keeping the heads of our trees clean. Even pruning, thinning, the removal of cross branches, &c., the keeping of the trees in order, prevents them from scrubbing off Moss, Lichens, &c. We are, therefore, bound to see that the tops of trees are kept clean; Mosses, Lichens, larvae, or insects smothered in soot, dust, and other dirt should all be scrubbed or scraped off, and, lest any incipient life remains, it is good practice to damb fruit trees over with some thick mixture, composed of such cheap ingredients as clay, soot, and lime.—D. T. FISH.

Fruit Rooms.

To keep fruit satisfactorily, a good store-room is absolutely necessary. In its construction two things should be kept in view—first, to build it so as to maintain an equable temperature, both in winter and summer; and, secondly, to provide means for free ventilation. In order to carry out my first suggestion, select a north aspect, build with hollow walls, and roof or thatch thickly with straw. Ventilation should be provided in the roof by means of sliding boards, which could be opened or shut at pleasure, and all windows should also be made to open. Some may think so much ventilation for a fruit-room unnecessary, but to ventilate freely at certain times is the only trustworthy way of keeping fruit successfully. Everybody knows that during, and especially after, frosty weather fruit "sweats," and it is nearly always after such weather that complaints are made as to its keeping badly; and, my experience is, that when ventilation is carefully attended to during and after such weather comparatively little fruit is affected. Of course, currents of air, continuously passing through the room are neither requisite nor desirable; for under

such conditions the fruit would shrivel, which I consider about as bad as decay. As a general rule fruit-rooms should be quite closed during muggy damp weather; indeed, at all times when the air is charged with moisture: but they should be opened the moment the air is drier, *i.e.*, should the fruit seem or feel the least damp. The kind of shelves which I think best, and would recommend, are such as are made of bars or laths, 4 inches wide and fixed about $\frac{1}{2}$ inch apart. Straw, paper, or other material should never be used under the fruit, which should be placed immediately on the boards, and, thus situated, air coming through the opening of the laths is permitted to play all round it. Owing to the changeableness of the weather and sudden fluctuation of temperature this has been, thus far, a bad season for keeping fruit in good condition, and when it is remembered that an equable temperature and dryness are indispensable requisites as regards good keeping, it is no wonder that so much of it has gone bad this year. Of Pears, the kinds that with us are keeping best, are Beurré Diel, Passe Colmar, Josephine de Malines, Ne Plus Menris, Winter Nelis, Easter Beurré, Beurré Rance, Comte de Flandre, Knight's Monarch, and Glou Morceau. The sorts which we are now using are Winter Nelis, Délices de Hardenpont, Passe Colmar, Beurré Diel, and Beurré Gris d'Ilver, all of which, without exception, are extra well flavoured, a circumstance doubtless attributable to the roasting weather to which they were subjected last summer. Apples generally keep better than Pears; and this season they have formed no exception to the rule. The kinds now in use with us for dessert are Ribston Pippin, Royal Russet, King of the Pippins, Hughes's Golden Pippin, and Calville Blanche. Kitchen kinds consist of Blenheim Orange, Wellington, Alfriston, Tower of Glamis, Warner's King, and Deux-ans.—W. WILD-SMITH, *Heckfield, Hants.*

Kitchen Garden.

At the time I am writing the earth is frost-bound and covered with a mantle of snow, which latter, in the event of a continuance of severe weather, will form the best and cheapest protector of vegetable life. Snow is, in fact, the only natural covering, and on no account should it be removed from any crop in the kitchen garden (except for the purpose of gathering it for immediate use); on the contrary, if the frost is likely to be severe, and, if it can be conveniently done, additional snow may be heaped over anything that requires extra protection. It may also be banked up round frames in which tender plants are stored, and where no artificial heat is available. Snow is the only covering that does not blanch or weaken the plants over which it is placed. If it is necessary to gather Spinach before the snow melts, some care will be necessary to avoid injuring the plants. A snow shovel, made of wood, will be found the handiest implement to clear off the snow, to be followed afterwards by a light birch broom. I need hardly say, all vegetables gathered in a frozen state should be placed in cold water to thaw them before use. A stock of roots, such as Turnips, Parsnips, Carrots, Artichokes, &c., for present use, should always be kept under cover. This would be a good opportunity for providing a sufficient stock for next year of Pea and Scarlet Runner sticks, and have them trimmed and sharpened ready for use. Heaps of decomposing rubbish should be turned over, lime and salt may be scattered amongst it to destroy insects and their eggs, and prepare it for going on the land at a favourable opportunity. Now that the old year is drawing to a close, the time seems to me peculiarly opportune for suggesting that we may with propriety take a retrospective glance at the past year; search our note books and memories, hunt up, in fact, and lay bare our errors, both of omission and commission (who is without them?), and endeavour to cull a lesson from the past for our future guidance. I must also beg to be allowed to suggest to all beginners the advantages to be derived from their keeping a calendar of operations, each for himself, as carried out in the gardens in which they may be employed; especially with regard to the kitchen garden; noting down daily the sowing and planting of each crop, with any other matters respecting their culture that may be thought desirable. To this may be added the daily readings of the thermometer, and observations on the weather generally, and the amount of rainfall, when it can be accurately done. I know these things are attended to by the young men in some gardens, and it might be advantageously done in all where they are employed; and the new year, being close at hand, will be a good starting point. This matter is the more urgent as, in many large gardens, a young man engaged in the houses has but few opportunities of becoming practically acquainted with vegetable culture, and I need hardly say that any one must derive a vast benefit from a system of note-taking. If persistently carried out, not only will it aid his memory, it will also strengthen his powers of observation, and tend to confirm in his mind a regular system or method of doing things which he will find of immense advantage in his future career.—E. HODDAY.

THE INDOOR GARDEN.

A NEW TWINING PLANT.

(CAMPSIDIUM FILICIFOLIUM.)

For particular purposes plants of elegant habit are quite as useful as those which bear beautiful flowers or gaily-tinted fruit, and few more graceful plants than this Fern-leaved Campsidium have found their way into English gardens. Our illustration gives an accurate representation of this plant, with the exception that the slender

Bull has raised it from seeds imported from the Fiji Islands. It has been awarded first-class certificates by the Royal Botanic Society, and also at South Kensington. B.

HOW TO GROW THE LISIANTHUS SUCCESSFULLY.

LISIANTHUS RUSSELLIANUS is one of the finest of decorative plants, but, owing to some supposed difficulty in growing it, it is now rarely seen. Mr. James Barnes, writing to the *Florist and Pomologist*, has recently described a mode of culture carried out by a neighbour of

Fern-leaved Campsidium (*C. filicifolium*).

shoots are often 2 or 3 feet in length, the elegantly cut foliage being of the brightest and freshest green imaginable. It may, however, be kept in a bushy state if required by means of judicious pinching, but this destroys its graceful appearance, and after all it is its trailing or twining habit which renders it so welcome an inmate of our plant stoves. In a cut state the long shoots are applicable for dinner-table decorations, or for draping the stems of March stands. It has not yet flowered in this country, and even the name is a provisional one, although it will doubtless never be known to horticulturists under any other. It grows well in a light, sandy, and rather rich compost, and when planted out it grows with tolerable rapidity. Mr.

his, Mr. Webber, of Exmouth, which is both simple and successful. Mr. Webber has only the convenience of a greenhouse and a two-light pit. In spring the pit is cleared of plants, the decayed materials turned out, and 2 feet 6 inches of well-wrought fermenting material placed inside. On this gentle heat is placed the *Lisianthus* seed, sown on light, open, sweet soil, and very lightly covered with sand, a bell-glass or piece of glass being put over the pot. As soon as the plants can be handled, they are pricked out in the same open kind of soil; and when they have grown a little they are potted into 60-sized pots. The fermenting materials having by this time become exhausted and sunk down, a temporary stage is formed close to the glass with a

few bricks and slips of boards, and on this the plants are now placed in saucers, the reason being that they are never watered on the surface of the soil, but tepid water is always supplied in the saucers. If the surface of the soil late in autumn and through the winter is watered, the plants are very liable to shank off or canker at the surface, and that, too, very suddenly. By the end of September the greenhouse is re-arranged with winter plants, when the warmest, lightest, and most sheltered place on the front shelf is chosen for the *Lisianthus* plants, which are there set in pans until the following spring, when they get a good shift, and are replaced on the prepared cutting bed, now again got in readiness with its fermenting materials. By this time most of the cuttings, &c., are removed, the young plants are ready for their final shift, and get more room till they begin to show bloom-buds, when they are again placed on the front greenhouse shelf to bloom. The clean pots used are drained fully one quarter of their depth with broken sherds; and the soil is healthy, sweet, well-pulverised, and tolerably light and rich, being composed of well-decomposed leaf mould, heath soil, or light turfy loam, a portion of well-decomposed cow-dung, and enough clean well-washed sharp sand, to keep all open, sweet, and porous, being always incorporated. In their full-growing season the plants may be watered with good clear liquid manure, never applying the water cold, or from autumn to spring, on the surface of the soil. The plants may be grown to any desired size, with the convenience of heat and room and large shifts. Mr. Webber's are finished off in 10-inch and 12-inch pots, and are noble healthy plants, with from three to four score or more open flowers on each plant.

WINTER BLOOMING BEGONIAS.

THESE are great favourites of mine, and I have often thought that their capabilities, from a decorative point of view, have never been half so well developed as is possible with very little extra trouble. Scarcely any other genus of plants is so distinct in habit, and but few will thrive so well under common-place treatment as these, and yet we find them well nigh banished from nine-tenths of the plant-stoves in the country, to make room for novelties of far less value from a gardener's point of view. Formerly they had the honour of a house to themselves at Kew, and few houses were more ornamental during the winter months, when their appearance was finer than at any other period of the year. Many of the best Begonias are profuse flowering plants, not the less acceptable because they persist in blooming all the year round; and then they are by no means particular as to the position or soil they occupy. You can grow the dwarf kinds in either pots or baskets, and they are equally at home, while the strong and tall growing kinds may be planted out and trained up pillars in the stove or warm conservatory, or on the back wall, or in any out-of-the-way place, just where your tender and fashionable novelties will not thrive. Recently some attention has been given to the half-hardy tuberous-rooted section, and for brilliancy of colour in the flowers, and freshness of foliage, many of these are unsurpassed; they will bloom on outdoor rock-work until cut down by the frost; but, if late-struck plants are planted out in the stove or other warm plant-house, they keep on blooming right through the winter, and supply plenty of cut flowers. As I have already stated, Begonias are suitable for pots, baskets, pillars, or rafters; but, no matter how they are grown, they are simply invaluable for the cut bloom they supply, and the flowers of Begonias are quite distinct from those of any other plants. For dinner-table decorations they are unsurpassed on account of the crystalline brilliancy of their colours, which show remarkably well under artificial light. The white kinds, as *B. spathulata* and *B. Dregei*, glisten like snowflakes, and the rosy, crimson, or scarlet-flowered species, are even more beautiful. For bouquets they are not adapted, as the flowers have a curious knack of dropping off suddenly from their stalks. Begonias are very readily propagated either by cuttings, leaves, or by division of the fleshy tuberous roots, and the soil they luxuriate in is a turfy loam and leaf mould, or rotten manure, with the addition of a little silver sand to keep the whole in a porous condition. The following kinds are great favourites, both with my employer and myself, and are grown here expressly for winter flowers. *B. Dregei*, a compact and bushy little species, about a foot in height, and nearly as much in diameter, which produces a copious supply of its white buds and

pure snow-like flowers among foliage of the most vivid green imaginable. It is valuable for furnishing the drawing-room stands, but it is rather too dense for dinner-table decoration. *B. spathulata*, an erect-growing plant, with rounded shining leaves and pearly-white flowers. *B. fuchsoides*, a well-known old favourite, that does well at the back of a sunny plant-stove; its long red shoots, clothed with bright leaflets of a metallic green tint, and enlivened by its gracefully-drooping racemes of heart-shaped coral-like buds and flowers, are admirably adapted for cutting, either for vases or other decorative purposes. I find this flowers best when planted out and trained up a wall. Our plant of it is 12 feet in height, and covers the entire back wall of a small plant stove, a position which it has occupied for nearly ten years. *B. hybrida multiflora* is a seedling similar in habit, with rosy flowers, but it is not equal to the last in beauty. *B. nitida*.—This is a strong-growing plant, which we grow up the pillars and walls of another warm plant-house—a sunny one—where it luxuriates to perfection, and is nearly always in bloom. I consider this the very best of all the flowering kinds, but it must be planted out in order to grow it to the best advantage. As a pot plant it is too straggling in habit to suit any plant grower. The foliage is large and of a pleasing bright green colour, while its large rosy flowers are produced in immense panicles, borne on long fleshy stalks from the apex of every leaf. For cutting, this is unequalled, and the flowers may be arranged along with *Calanthe Veitchii*, *Laelia anceps*, *L. autumnalis*, or the snowy *Cologyne cristata* without losing any of their beauty by the contrast of such lovely rivals. *B. Saundersonii* is a well-known winter-bloomer, with bright green foliage, good compact habit, and bears a profusion of deep rosy flowers in drooping clusters. This and *B. insignis* are valuable for pot culture. I have about two dozen plants of each in 48 and 32-sized pots, and they are just now, together with a large batch of *B. Dregei*, admired by everyone who sees them. *B. Wagneriana* and *B. hydrocotylifolia* are both good winter bloomers, but one of my favourites is the old *B. manicata*, which, as a table plant, is, I think, unsurpassed in its way. Well-grown plants in flat pans (I use these for this species, because its fleshy rhizomes require a considerable surface to develop themselves), are valuable for table decoration. When well grown the plant is about 1 foot or 14 inches in height, and from the axil of nearly every leaf rises a fleshy semi-transparent pale green or pink-tinted stem, about 16 or 18 inches high, and these branch into compound panicles, the ultimate divisions being very slender, and each terminated by a delicate rosy heart-shaped tint or flesh-coloured flower. There is a delicate lace-like beauty about the inflorescence of this plant when seen under artificial light that makes it a great favourite with ladies. Another splendid plant, either for pots or planted out as a climber, is *B. Daviesii*, a free-blooming kind, seldom seen in private collections; I was fortunate in obtaining cuttings from the Kew collection some years ago, and have found it a most valuable plant for winter decoration. In habit it resembles *B. Saundersonii*, but its flowers are much larger, and, if possible, it is a more profuse bloomer. All the above are well worth growing by all gardeners who require a supply of decorative plants and cut flowers during the duldest portion of the year.

Whalley Range.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pandanus Veitchii at Drumlanrig.—This is the finest of all the Screw Pines. Excellent specimens of it may be seen in the plant stoves at Drumlanrig, where they are grown in 14-inch pots, well drained and filled with a compost of strong loam, peat, and silver sand. Its leaves are broad and massive, and their colourings rich and distinct, the dark green and white stripes being well defined. This *Pandanus* is a like ornamental in the plant stove, and on the dinner table when not too large.—M. J.

Ipomœa Horsfalliæ in a Pine-stove.—As a stove climber, to flower from September till February, this has no equal. The back wall of one of the Pine-stoves at Drumlanrig is covered with it to the extent of 60 feet, and the great clusters of crimson-scarlet flowers which it produces have a very striking effect. It is useful in a cut state, and single blooms of it are favourites with ladies for hair ornamentation. Buds of it before they expand are nearly black, and form a nice contrast with the open flowers. The foliage, too, which is a very dark green, forms a good covering for a wall, even when the plant is not in bloom. This *Ipomœa* grows freely in nearly any kind of soil with which plenty of sand is mixed.—J. MUIR.

THE FRUIT GARDEN.

PINE GROWING AT DRUMLANRIG.

PINES are grown very extensively, and to perfection, at this place. Mr. David Thomson, the highly talented gardener there, has long been justly regarded as one of the best Pine growers in the country, and his present productions fully sustain his reputation. While at Archerfield, the Pines there under his care were ever worth a visit, so perfectly were they developed in every way—some of the Smooth Cayenne fruit attaining the handsome weight of 11 lb., in low pits—and those who had the privilege of seeing them will understand what the Drumlaurig ones are like when I say they are now up to the Archerfield standard. This has never been the case at Drumlaurig until now, for, although Pines were cultivated there for years before Mr. Thomson took their management, they were of a very ordinary character some six years ago. The stock there now has no connection with that of the past, either in lineal descent or mode of cultivation. The pots and plants are about half, while the fruits are double, the size they formerly were. These are all improvements and great *desiderata* with the intelligent Pine grower. The Pine accommodation at Drumlaurig is spacious, there being numerous houses and pits for the plants in their different stages of growth; but the circumstances under which they are grown are not of the most favourable kind. Nearly all the stoves are glazed with rough thick-rolled plate glass. This has its advocates and advantages, which, however, do not exist at Drumlaurig, where the sun is seldom visible more than two days in seven throughout the entire year. Under this obscure glass it is as if they grew continually under shading; and those who know anything about Pines are aware how liable they are to become drawn and unhealthy when this is the case. I did not see an unhealthy or drawn plant there. Every leaf was of a deep blackish-green colour, which is not only pleasing to the eye of the Pine grower, but to every one who admires fresh-coloured vegetation. Queens for fruiting early and later in the season were plentiful. Five degrees more of heat than what they were resting in would have started every plant into fruit in a fortnight. I had to look closely into many of them to convince myself that they were not in fruit, they were so open in the centre. The plants were exceedingly dwarf, thick around the stem, with short leaves, nearly as thick as those of an Agave. It must be remembered that these plants were not grown in large day-light houses, but in narrow pits, with their sashes glazed with the rolled plate glass I have mentioned; another large house contained the autumn fruiters, many of them were cut, and there were dozens of them still to cut—these consisted of Smooths, Charlotte Rothschild, and Prince Albert; 5 lbs., 6 lbs., and 7 lbs., was the average size of the finely formed fruits; no large quantity was ripe at once, but they succeeded one another. Large batches of this kind are often collected from other beds as they show fruit (I have a houseful in fruit together); but the whole of those I speak of started into fruit successively, and not a single plant had been removed from the time they were first potted into the 12-inch pots in which they were ripening their fruit. The appearance of this house before any fruits were cut from it must have been very grand. The plants were of the same substantial caste as the Queens. Strange to say, the crowns were perfectly well proportioned, and in no way elongated. In other houses the fruit was swelling to succeed those nearer maturity. Those just in the embryo were of vigorous formation, and promised well for future development. The suckers were splendid examples of what young stock should be. These were in 6 and 8-inch pots; they are afterwards shifted into others of the fruiting size. The soil used is a yellowish fibrous loam, mixed with a quantity of pure ground bones; leaves, which can be plentifully collected from the woods and parks, are made use of for plunging material. Mr. Thomson gives preference to the tan over these, and, now that he has got his own excellent system introduced, he intends using this substance more than he has hitherto done.

J. MUIR.

PROTECTING STRAWBERRY PLANTS IN WINTER.

NOTHING in connection with early Strawberry culture is more important than protection during the late autumn and early winter months, as, however well they are managed through the summer, neglect in this respect generally proves baneful to the plants, and prevents anything like real success. Where a large quantity of plants is grown for forcing it is very often difficult to procure frame room to the necessary extent. I am, therefore, having a long span-roofed pit erected for the purpose. Such a pit has been used for some time by my friend Mr. Owen, of Broughton Hall, in this neighbourhood, who grows and forces Strawberries with greater success than anyone I know. As soon as the heavy autumn rains set in the

plants are carried to their winter quarters and packed closely together with leaves, the object being to retain a certain amount of moisture, at the same time excluding all heavy rains and frost. The advantage of such a protection will be evident enough to anyone acquainted with the management of Strawberry plants for forcing. I have often noticed good plants, well grown in summer, half ruined during the months of October and November. Very often they are taken to the bottom of a brick wall, piled one above the other, and allowed to become dust dry, so that the hand could be inserted between the side of the ball and the pot. Now, I will guarantee that the same plants packed with leaves in a cold pit or frame, as described, will bear double the quantity of fruit the following March or April. I have also noticed, too often, the front shelf of a Vinery or Peach house (where perhaps a little fire-heat is kept up to protect bedding plants, &c.) occupied with Strawberry pots, subject to the same baking above described; an earth pit, or some loose slabs temporarily erected and covered with some old sashes will answer the purpose far better. We invariably hear of success, seldom of failures; after succeeding well with early and mid-early Strawberries last season I was much disappointed by having about 300 Sir Charles Napier's very much injured by the heavy frost in February, when I fancied all was safe, the consequence being that although the plants were only meant to come in before those outside, they only have one-third of the crop from those early forced. Little mishaps set one a-thinking, and having planted a quantity out of 3-inch pots the previous autumn, I had them transferred from the open ground into some frames over decayed hot-beds, where there was just the slightest heat; watered well a day before they were lifted, they were moved with fine balls, and continued growing, although the flower spikes were being thrown up, and they have borne a moderate crop of handsome fruit, which filled in what would otherwise have been a blank, before Strawberries were gathered from the outside. We sometimes err on the side of quick forcing; I believe success to be more a question of time, all things being well managed previously. I know no fruit more likely to be injured by quick forcing than the Strawberry. My first batch of 500 are put in about December 1st, and we gather fruit from the 15th to the 20th of March; indeed, I have put the first batch in on the 1st of November, and did not gather before the 20th of March; but I should state that the variety I use for early work is what is called The Duke in this neighbourhood—Duc de Malakoff or Vicomtesse Héricart de Thury, which latter is its proper name. Black Prince can, of course, be gathered much earlier, but the Prince so deceived me once that I reject him now for indoor work, and I have substituted The Duke, allowing plenty of time until the fruit is well set, and then they are driven along rapidly. I only force four varieties to any extent, viz., Duc de Malakoff, Oscar or Wilmots, Sir Harry, Sir Charles Napier, and British Queen.

W. HINDS.

Otterspool Gardens, Liverpool.

HOW TO PREVENT THE SYRIAN GRAPE FROM SHANKING.

MR. MUIR, after writing (see p. 453) of late Grapes, says, "As whites, White Lady Downes, Trebbiano, and the true Syrian are good sorts." I should be glad to obtain further information respecting the Syrian, especially as to its liability to shanking, and the proper treatment for preventing or curing this very serious defect. Six years ago I planted a Vine of this variety in a mixed late house along with Muscats, Mrs. Pince, Gros Colman, Aramon, and White Toquay. It has grown vigorously, making good short-jointed wood, and producing plenty of fine large bunches, which have every season gone on as well as could be desired till they ought to be on their last stage of swelling, when they shank off all to pieces, leaving rarely a dozen berries on the remains of each bunch to ripen. The few berries that are left are large, oval in shape, colour well, and have a very high flavour. The Vine has never been over-cropped, as I have not yet obtained a single bunch from it, and, when thinning, I never leave more bunches on it than it ought to carry. I have been told by an old gardener that the Syrian is apt to shank. Can you suggest a remedy.—P. Q.

[The Syrian should not shank where Muscats and Gros Colman succeed, as they are much more liable to shank than it. Shanking is by no means the common habit of the Syrian. In a general way, with its free-growing character and robust constitution, it is quite free from failings of this and all other kinds. Is it the only variety in the house so affected? If the whole are subject to this malady the matter would be easily understood. From my acquaintance of your correspondent's low-lying neighbourhood, it is one very likely to be morbid to the Vine, especially if efficient drainage is not provided. Bad drainage is a great cause of shanking, and must

undergo the first consideration and examination. In cases where a whole houseful of Vines are affected, the soil which forms the border must be taken out to the depth of 3 feet, leaving only enough to protect the principal roots about the base of the stem. When all is cleared, the bottom should be completely covered with 3 inches of concrete, at an incline from the house of 1 inch in 24 inches, to the extreme front of the border, where a large main drain should be placed in a position to convey away the water at once. Place rows of 3-inch drain tiles 12 feet apart to run from the house into the main drain, fill up between these with broken stones, and cover the whole over with fresh-cut turf, laid grassy side downwards. The formation is then properly complete and ready for the compost. If not more than six years old, the same soil, with a liberal addition of substantial fibry turf and $\frac{1}{2}$ -inch bones, will do again. Into this the Vines soon root freely afresh, and, if Syrian, or any other kind, shanks after such efficient precautions, then it is very evident that the vicinity is one unsuitable for that variety. Instances of this kind are to be found all over the country; but not often with the Syrian; however, when such is the case, grafting or inarching is a remedy for the evil. Muscat of Alexandria is one of the best stocks for it, and with this in his house "P. Q." will have no difficulty in profitably disposing of his Vine, with every certainty of success in future. Grape shanking is not one of those inconveniences which the application of a little more or less air, or a few more degrees of heat at a certain time will remove. It is a serious functional derangement, which can only be cured by radical treatment. A short time ago I saw the Syrian in great perfection at a considerable distance from here, and had the grower of it to choose, Syrian is not the first variety he would dispense with.—J. MURK.]

PEARSON'S GOLDEN QUEEN GRAPE.

PERMIT me to supplement the numerous remarks which have appeared in your pages upon the merits of this Grape, as I feel certain it is destined to occupy a very prominent position as a generally useful late Grape. I never saw a Vine and its produce possessing such a combination of true late winter characters as those so conspicuously shown in Golden Queen; I feel at a loss which of its qualities to admire most, and cannot give any one preference over another. Its constitution is very robust; the leaves are thicker and of greater substance than those of any other kind of Vine; the wood is not very thick, but free in growth; it ripens well in a cool Fig-house, and produces fruit in a most prolific manner. The original rod, which is four years old, had sixteen bunches on it this season, and it is only about the same number of feet long; six of them were still hanging when I saw them a few days ago, and had an opportunity of noting their strikingly handsome appearance. The flavour is very superior, as described by Mr. Ingram (p. 473), and, altogether, its character, so far as I could learn from inquiry and minute examination, which is the best of all tests, is quite irrefragable. I tasted it last autumn, when some berries of it were sent to a friend of mine, and the estimate I formed of it then, although of no mean description, was far short of what I really found it at Chilwell. Its stock there might well have been sent out this winter, but Mr. Pearson, to avoid disappointment in any form whatever, is going to cut them all back, that all may be strong next year. Messrs. David and William Thomson, Mr. Speed, Mr. Douglas, and many other noteworthy horticulturists, are justly praising it as one of the best late white Grapes extant. M. J.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Scotch versus English Pots.—I have sometimes found a single pot amongst a large number of accurately 10-inch ones measure 9½ inches, but this is not the general size. Strictly adhering to sizes, I cannot understand how an English 12-inch pot only measures 10 inches, as stated by your correspondent (see p. 578). I have ordered a quantity of English pots, by name and measurement 12 inches, and if for these I receive 10-inch ones, I certainly will not consider them 12-inch ones. Ten-inch pots in Scotland are made no more perpendicular than any other size made there; and to assert that any or all of them are made in this form is a mistake.—J. MURK.]

The St. Germain Pear.—What treatment do you recommend for a large bush tree of this Pear, which yields fair and large crops of nice-looking, but perfectly tasteless fruit? The tree is too large to move. Our garden is a sheltered one, and its soil, which is light, seems to suit other Pears very well, as we generally have good crops.—E. L. J. [The St. Germain is never much better than a stewing Pear, even in such a fine summer as the past. As the tree is too large for shifting, perhaps root-pruning some of the largest outlying roots might have the effect of making the fruit smaller and better flavoured. The best way, however, in order to make sure of getting some good fruit off the tree, would be to cut the branches off in the spring and insert grafts of some good sorts on the stumps left. They should be cut off at a suitable height for grafting, and the grafts should be inserted between the old wood and the bark. When tied firmly round with matting and clayed over, such grafts will grow rapidly, and soon make a fruitful tree.—W. TILLERY.]

A RAT-PROOF FENCE.

GRANARIES, corn cribs, or poultry houses, may be made rat-proof, by means of a wire fence which we here illustrate, and for which we are indebted to the *Journal d'Agriculture Pratique*. This fence has been introduced with perfect success, into the Garden of Acclimatation in

Fig. 1.—End of Fence.

Paris, and into our own Zoological Gardens, for the purpose of preventing the depredations of rats. No rat can surmount this fence. It is made of thin wire bars placed an inch apart, and affixed to heavier cross bars; the ends of the bars being curved outwards, as shown in fig. 1. When the building to be protected is placed upon the ground, and it is desired to prevent rats from undermining it, two rows of bricks or tiles are placed beneath the fence, one in an upright position, and sunk a few inches beneath the surface, and the other horizontally and projecting outwards, forming a bench. When the rats dig down to burrow beneath the building, they follow the first tile until they meet the second. Being stopped here, they burrow along the angle formed by the two tiles until they are tired, without being able to penetrate beneath the building. If they attempt to climb the wires, they get into the gallery formed by the upper curve, but can go no further. The fence, of course, is made of such a height that a rat cannot leap over it. In the Garden of Acclimatation, the fence is about 2 feet in height, and is found perfectly effective. Fig. 2 shows a piece of the fence complete. This contrivance is also used to entrap rats, which it does in large numbers. A small park or enclosure is surrounded with this fence, protected at the bottom with tiles as already explained. An opening is made, by which the rats may enter but cannot return. Seeing a possible escape by means of the fence, they enter readily, but once within they discover that some

Fig. 2.—Fence complete.

men know more a rat. There are many modifications of this simple contrivance, which will, doubtless, occur to our readers, by which farm buildings, grain stacks, and other places which suffer greatly from rats, may be made secure from their depredations.

Limekiln Heating.—Mr. John Cowan writes to us to state that the system of heating announced as invented originally by Mr. John Collis, has nothing in common with Mr. Cowan's system. Mr. Cowan adds, that, according to Mr. Collis's own statement, his limekiln is an open one without a chimney, and, therefore, quite distinct from those constructed in many gardens by Mr. Cowan.

Messenger's Patent Valves.—For safety and convenience these valves are unsurpassed. The stop-valve inside is worked by a small outside wheel in such a way that it may be set to the eighth part of an inch or turned full on with the greatest facility, and it always remains steadily in whatever position it is put, for any length of time. I never knew one of these valves to get out of order—an important matter, for the boilers themselves may as well be out of order as the valves. Some dozens of them are in use at the Tweed Vineyard, and all of them work satisfactorily.—J. MURK.]

Consumption of Fruit in Paris.—In Paris (we learn from *Les Mondes*) the quantity of fruit consumed annually is something enormous. There is brought annually into that large city more than 5,000,000 kilos of raisins, the duty on which amounts to about 300,000 francs (at the rate of 5 francs 75 cents per kilog). The cultivation of Grapes for raisin-making in France is being considerably extended.

MINERAL MANURES.

UNDER this head we advert to those manurial substances which are obtained from the crust of the earth and which are spoken of as mineral, in contradistinction to farmyard manure, night-soil, shambles-offal, and the like, which are of organic origin, and result from the decay, secretions, and exuviae of plants and animals. These mineral manures play an important part in modern agriculture, both in top-dressing for pastures, and as feeders and stimulants to grain and green crops. Though generally spoken of as "mineral," most of them (peat, marl, chalk, coprolites, osite, guano, &c.), owe their origin to organic agency, but are now separated from "organic" because they are more or less mineralised, and form component portions of the rocky crust. However much the soils of a farm may be benefited by admixture and drainage, they cannot continue to be cropped without the application of manures. Every crop, as may be seen by an analysis of its ashes, takes so much mineral matter from the soil on which it grew. In course of time this mineral matter will become exhausted, and the plant, deprived of its appropriate nourishment, will cease to flourish. To maintain the standard of fertility is the great object of manuring; and whatever will restore to the soil in a state of solubility what the plant has withdrawn—for plants can take no food in by their roots and spongeoles, save in solution—becomes a manure. The manures obtained from the mineral kingdom are very numerous, but the most important and abundant are those of a carbonaceous, calcareous, and saline nature, yielding to the growing plant carbon, silica, lime, soda, potash, and other essential ingredients. Different crops require, of course, different manures, and what may start Turnips into luxuriant growth may have comparatively little effect upon a field of Clover. The mode and amount of application belong to the art of husbandry; geology deals only with the nature, occurrence, and abundance of the manurial substance. Numerous experiments, however, have been made with the mineral manures, and the special results recorded in the "Journal of the Royal Agricultural Society of England," and in the "Transactions of the Highland and Agricultural Society of Scotland," to both of which the cultivator may refer with advantage.

Carbonaceous Manures.

First among these mineral manures we may notice peat, which occurs largely as a surface accumulation in most situations in all temperate and coldly-temperate countries. In our own country, especially in Scotland, Ireland, and the northern counties of England, it can be obtained in inexhaustible supplies. It is strictly of vegetable origin, contains little earthy matter, is found from the "turf" now growing to the old compact "peat," 20 or 30 feet in depth, and often covering areas thousands of acres in extent. When dug up and exposed to the weather, it crumbles into a dark pulverulent mass, and in this state, either alone or in admixture with quicklime, has been applied with beneficial results to stiff loams and clays. It has been also fermented in admixture with farmyard manure, thereby not only increasing the mass, but absorbing and fixing the ammonia which escapes during fermentation. And in many cases it has been charred by combustion in smothered heaps, and the dry ashes applied with excellent effect to soils deficient in vegetable or carbonaceous matter. According to Professor Johnston, "charred peat forms, likewise, an excellent absorbent for the liquids of the farmyard and the stable, and for drying up dissolved bones." Coal-dust or "slack" is sometimes spread on cold stiff clays, but with little effect, we presume, beyond that of cutting them up and rendering them more friable. Coal-ashes and the light porous coke from shale retorts, tell with better effect; and soot, which is merely charcoal in a very fine state of sub-division, is often employed with wonderful results as a top-dressing to pastures, as well as to grain crops. Its fertilising properties are mainly due to the ammonia, sulphate of lime, nitric acid, and certain other ingredients which it contains.

Calcareous Manures.

Marl, which occurs in lakes, or is found at or near the surface, in bogs and morasses, the sites of obliterated lakes, is a soft earthy carbonate of lime, resulting from the shells of fresh-water molluscs (*Paludina*, *Limnea*, &c.) and other minute animal organisms. It generally occurs in layers and patches, from one to several feet in thickness; and when the shelly matter predominates, it is spoken of as shell-marl; where the silty matter prevails, as clay-marl. It is now seldom used; but about the beginning of the present century was largely dug or dredged up, and applied in a raw state as a top-dressing to pastures, or as a corrective to clayey and peaty soils. Another calcareous substance often applied with beneficial results to stiff clayey soils is the shell-sand (shelly, coralline, and other limey *débris*) which occurs largely along certain portions of our sea-coast. Consisting, for the most part, of carbonate of lime, with a certain amount of the phosphate, it not only acts as a breaker-up of

the stiff-textured clays, but from its gradual solution by the carbonated rain-water supplies to the soil an important element of fertility. Considering the vast amount of this material which lies scattered along our shores, and which is easily manipulated, it looks like ignorant neglect on the part of our farmers that so little of it should be employed. In the "Report on the Geology of Devon, Cornwall, and Somerset (1839)," it is stated that, in 1811, Mr. Worgan estimated the cost of the land carriage of this sand in Cornwall at more than £30,000 per annum. Large quantities are obtained at the Dunbar Sands, in Padstow Harbour, the annual amount estimated at 100,000 tons. It has been calculated that 5,600,000 cubic feet of sand, chiefly composed of comminuted sea-shells, are annually taken from the coasts of Cornwall and Devon, and spread over the land in the interior as a mineral manure. It is also applied in some of the western islands, where the shores are thickly fringed with it, with beneficial effect to hill pastures and peaty soils; but notwithstanding these facts and figures, the substance, considering its abundance and obvious utility, is strangely neglected. It abounds on the shores of France, and, according to M. Burat, is highly valued as a cheap and efficient manure, as well as an improver of stiff clayey soils. Like marl and shell-sand, the upper chalk of the south of England (a soft earthy carbonate of lime) is sometimes broken down and applied to clayey soils and pastures. Applied in this way, at the rate of thirty and forty loads an acre, it acts chemically as a manure, in rendering the soil richer, and mechanically, in rendering it lighter and more friable. Though now a lime-rock of great extent, and several hundred feet in thickness, chalk is mainly of organic origin—about 80 per cent. of its mass being composed of the minute shields of foraminifera, similar to those now forming the calcareous ooze of the mid-Atlantic. Gypsum, or sulphate of lime, is applied in a similar way to Grass-lands in this country, at the rate of 2 or 3 cwt. per acre; but in Germany and the United States of America it is largely used in general husbandry, and with marked effect on crops of Maize, Pea, Bean, and Clover. Gypsum occurs crystallised and massive, in various formations; but the most extensive beds are found in connection with rock-salt in the new red sand-stone, and alternating with the clays and marls of tertiary basins. In Britain abundant supplies can be obtained in Chester, Nottinghamshire, Derbyshire, Westmoreland, and other localities; and not a little of that which is raised finds its way to the artificial manure factories. But while the carbonates of lime (marl, shell, and chalk) are applied in the raw, mild, or uncaustic condition, limestone in general is more extensively used in the caustic or quicklime state. In this condition it is extensively used, not only as a top-dressing, but incorporated in the soil as a feeder, dissolver, and stimulant—its effects being partly mechanical and partly chemical. "They are mechanical," according to Professor Johnston—"as by slaking, the burned lime can be reduced to a much finer and more bulky powder than the limestone could be by any mechanical means; and they are chemical, inasmuch as by burning the lime is brought into a more active and caustic state, and is, at the same time, mixed with variable proportions of sulphate and silicate of lime (evolved in the kiln) which may render it more useful to the growing crops." The limestones are largely developed in the British Islands, and occur in all the geological systems—metamorphic, silurian, devonian, carboniferous, permian, (magnesian limestone), oolitic, and cretaceous. There are few districts that cannot command a supply within their own area, or, at all events, at comparatively little expense from some contiguous area. Besides the carbonates and sulphates of lime, the phosphates are also extensively used and highly valued as mineral manures. A crystallised variety under the name of apatite (56 lime, 44 phosphoric acid) is obtained from veins in the older rocks; is of various shades of colour, white, yellowish white, and greenish white; stands 5 in the scale of hardness, and has a specific gravity of 3 or 3.25. It occurs in various countries, Norway, Spain, Bohemia, Switzerland, France, &c., and is often accompanied by a massive variety, which is known as phosphorite. This phosphorite is the more abundant product, and consists of phosphorite of lime Si , fluoate of lime 1.4 , with iron oxide and silica. These hard phosphates, of which there are several varieties, require expensive mining and reduction, and hence they have given way, in a great degree to the phosphatic nodules and concretions of the greensands and tertiary formations. Phosphatic nodules, coprolites, or "cops," as they are familiarly termed, are occasionally concretions round bones and true coprolites or fossil excrement; but, generally speaking, they are mere nodular or concretionary masses of a soft and earthy texture. They are found in the greensand and crag formations of England, and also in the greensands of France, in layers and in sporadic deposits, from a few inches to several feet in thickness, and when moderately pure contain about 50 per cent. of phosphate of lime. Well-cleaned examples from Cambridgeshire have been found to yield—phosphates, 61, carbonates, 28, insoluble silicious matter, 7, and water, with

traces of organic matters, 4. Their dissemination in the crag and greensand is rather uncertain; but £80, £100, and even, it is said, as much as £400 per acre has been paid for the right to dig and remove them from the estate. According to Hunt's "Mineral Statistics," the amount raised in 1872 was estimated at 35,000 tons, value £50,000. Similar deposits of a much more extensive nature occur in the tertiary formations of the Carolinas, New Jersey, and Georgia, and are largely used in the United States of America, as well as imported into Britain for the manufacture of artificial manures. Picked, crushed, and treated with sulphuric acid (and variously mixed with other substances), they form the "super-phosphates" of commerce—every manufacturer adopting his own treatment and proportions of admixture. Whatever the admixture, the great object of the sulphuric acid is to convert a considerable part of the insoluble earthy phosphate of lime into sulphate and soluble superphosphate. Plants take in no food save in a state of solution, and the main value of a manure (other things being equal) is its capability of being dissolved by the moisture of the soil according to the requirements of the crop to which it is applied. What is termed osite, Sombbrero guano, or Sombbrerite, is another phosphate of lime used also in the manufacture of artificial manures. It is obtained from Sombbrero, one of the West India Islands—an islet about two and half miles long, from a half to three-fourths of a mile wide, and not more than 20 or 30 feet above the level of the sea. The islet is entirely composed of this substance, which consists of a breccia of bones of turtles and other marine vertebrata, coral *débris*, &c., collected when the area was a shallow shoal, and before its elevation above the water. Since its elevation the rains have carried down through the mass the dissolved droppings of birds (guano), and cemented the whole into a compact mass of valuable phosphate. The true guano (huano of the Peruvians), though of animal origin, has undergone so much alteration by internal chemical change, and occurs in such masses, that it may, without much error, be treated as a mineral manure. It consists mainly of the droppings of countless sea-fowl, intermingled with their skeletons and eggs, the decomposed bodies and bones of fishes, seals, and other marine creatures frequenting the islands on which it is deposited. Though obtained principally from the rocks and islets that stud the Bolivian and Peruvian coasts, it accumulates in all rainless regions—the drier the latitude, the thicker and richer the deposit. On some of these islets it is found in great thickness (40, 60, 80, and in some places, according to Dr. Scherzer, 120 feet), and, considering, its necessarily slow accumulation, must be of vast antiquity. The digging of the deposits and the frequency of modern shipping has greatly disturbed the birds, and much less is now deposited than in former times. About five-and-twenty years ago, considerable quantities were obtained from Ichaboe, and other places on the west coast of Africa; but as absolute dryness is necessary to the preservation of the ammoniacal salts, which constitute the chief value of guano, these supplies brought little more than half the price of the Peruvian, and we believe are now entirely exhausted. The amount imported into Britain from Peru, since 1844, is estimated at five and half million tons, valued at sixty-four millions sterling; but this rate of importation cannot long continue—for, according to the estimate of the British Consul at Callao, in 1873, the whole of the exportable guano which Peru had then possessed did not much exceed three million tons. The following analyses, from Johnston's "Agricultural Chemistry," show the relative composition of American and African guanos:—

	Peruvian.	Bolivian.	Ichaboe.	Saldanha.
Water	13.09	6.21	16.71	18.35
Organic matter containing ammonia	53.17	55.52	46.61	22.14
Common salt and sulphate of soda	1.63	6.31	12.92	5.73
Carbonate of lime	4.14	3.87	0.27	1.49
Phosphate of lime and magnesia	23.54	25.68	22.40	50.22
Sand	1.30	1.71	0.52	2.02

Saline Manures.

Besides these calcareous minerals and guanos, a considerable number of saline substances have recently been employed with wonderful effect, both as top-dressings and as incorporated manures. The chief of these are sulphate of ammonia, carbonates of potash and soda, nitrates of potash and soda, sulphate of potash, common salt, sulphate of soda, silicates of soda and potash, and sulphate of magnesia. Most of these are manufactured artificially, as sulphate of ammonia, for example, from the ammoniacal liquor of gas and paraffin oil works; but many also occur in a crude or impure state in deposits often of considerable magnitude. In and around salt lakes like those of Central Asia, along dried-up lakes and deserts like those of Asia and Africa, and over extensive reaches like the salinas of South America, these salts occur in abundance, and constitute important articles of commerce. The desiccated lakes of Central Asia have been described by various travellers as flat expanses, covered during the dry season with white

efflorescences of various salts, from a few inches to 2 or 3 feet in thickness, and over which their horses had to pass, treading up to the knees among crackling crystals of great beauty and purity. Mr. Shaw, in his recent travels in Tartary, rode through desiccated lake sites, covered with a thin crust of sandy soil, but consisting beneath of beds of common salts, and salts of soda and potash, varying from 1 to 3 feet in depth, and often of almost transparent purity. The salinas of South America, which at present yield our main supplies, are described as superficial deposits, occupying extensive plains on the Pacific, or rainless side of the Andes, and usually covered with a white saline efflorescence or crystalline incrustation. They occur at all elevations, from a few feet to several thousand feet above the sea level, and are evidently the remains of old sea reaches and lagoons that have been desiccated by the upheaval of the land. They extend for about 600 miles north and south, but find their greatest development between latitudes 19° and 25° south, and at distances varying from 10 to 40 miles inland. The usual salts occurring in these salinas, as in those near Iquique and the desert of Atacama, are common salt or muriate of soda, sulphate of magnesia, sulphate of soda, sulphate of soda and lime, soda-alum, magnesia-alum, gypsum, anhydrite, along with chloride of calcium, iodide and bromide of sodium, carbonate and nitrate of soda, and in some places borate of lime and borax. The saline plain of Taramugal, for example, which is 3,000 feet above the sea-level, consists, in some places of many feet in thickness, of sand indurated with salt, in others of soft sand with crystals of nitrate, and occasionally of true caleches of concreted soda and stony *débris*. These saline sands and gravels are dug and lixiviated on the spot, the liquor evaporated, and the crude salts exported at the rate of many thousand tons per annum. We have said nothing of artificial manures, whose name is legion, but restricted our notice chiefly to manurial substances which occur native in the crust of the earth. No doubt these substances enter largely into the artificial manures of commerce; but other substances of an organic nature are also employed, taking the manufacture more under the head of chemical technology than of applied geology. Indeed it is often difficult to say what enters into the composition of many of these artificial manures—ashes, peat-mould, sawdust, gypsum, chalk, salt, sand, loam, and other substances still more worthless and objectionable than the worst of these.

In the preceding paragraphs we have endeavoured to explain as fully as our limits will permit, the relation that subsist between geology and agriculture. Those refer to the soils upon which the cultivator has to operate, whether they be soils of disintegration, resulting from and directly affected by the rocks on which they rest—or soils of transport, which have been weathered and wasted from distant rocks and laid down by various agencies in the situations they now occupy. They refer also to the sub-soils on which the arable soils rest, and the influence these may exert on their drainage, texture, and fertility. Much of the agricultural surface of Britain consists of what the farmer terms "made soil"—soils reclaimed from stony bouldery wastes, heathy, peaty moorlands, and plashy swamps and morasses, by blasting and removal of boulders, by turfing and burning, and by draining. But whether reclaimed or natural, soils are not alike fertile, some being too sandy, too clayey, too peaty, or too calcareous; and the question arises, How far their defects may be remedied by admixture with other soils, so as at once to impart to them the necessary composition and texture? Besides fertile admixture, there also arises the question of drainage, by which the superfluous moisture may be got rid of most effectually, and at the cheapest rate, so as to render the soil drier and mellow, and more easy of cultivation, more friable, and thereby more permeable by air and moisture, and deeper and softer, that the crops may readily extend their rootlets in search of the nourishment they require. As this nourishment or manure is largely obtained from the mineral kingdom, it becomes necessary, in the next place, to advert to the more important of the mineral manures—treating of their geological nature, their abundance, and the facilities with which they can be obtained. Whether carbonaceous, calcareous, or saline, these mineral manures are yearly assuming a greater importance; hence the value of an intelligent acquaintance with them to the practical agriculturist. Considering, therefore, the nature of soils and sub-soils, their composition, texture, and relations to the subjacent rocks; and considering also the importance of drainage, and the application of mineral manures—all of which involve some acquaintance with the materials and structure of the earth—the relations of geology to agriculture must be sufficiently obvious and deserving of study alike by the landlord and farmer.—*Economic Geology.*

The Field relates how a root from an Elm tree filled up a drain tile 150 yards distant.

THE GARDEN IN THE HOUSE.

A DRAWING-ROOM PLANT STOVE.

We have lately seen a heated plant case of rather a novel character, manufactured by Messrs. Dick Radclyffe & Co., of High Holborn, in which both heat and moisture are completely under the control of the cultivator, its perfect action being regulated by a very ingenious application of mercury in a manner analogous to that employed in the "Victoria thermometer," brought into public notice some years ago. Either gas, oil, or spirit lamps may be used for heating purposes in this case, the heated water from a small water Jacket boiler being circulated through leaden pipes, by which means a genial bottom and top-heat are both secured. The inventor, Mr. Boyle, informs us that he has succeeded in growing most of the *Anaclochili* in a case of this description, while many other foliage plants, Orchids and *Ferus*, of the most tender description, may be grown in the drawing-room by means of this invention. Those who are aware of the results attainable even in an unheated Wardian case, or glass shade,

Boyle's Heated Plant-case.

will at once see that here an immense field is opened out to them in the culture of the smaller stove plants, and its introduction indicates a new era in domestic plant culture. B.

Hanging Basket of Cut Flowers.—If fitted up lightly these have a pretty effect; indeed, as far as appearance goes, they are far more effective than those furnished with growing plants, but require more attention, as they have to be constantly refilled with cut flowers; but, again, they do not require such constant watering, which, in a sitting room, is an advantage not to be overlooked. Baskets which are to be used for cut flowers should be fitted inside with a zinc basin, the shape and size of the basket; the outside the basin should be painted the same colour as the wire-work, and should have at the bottom a hole for drainage, as I should advise that *Selaginella denticulata* be grown over the surface of the sand with which the basin is filled, and in which the stems of the flowers are to be inserted. As to what flowers should be employed, that will, as a matter of course, depend on the season of the year, and on the resources of the decorator. Round the outer edge, long sprays of drooping plants should be inserted, so as to hang down gracefully all round. There are many flowering and foliage varieties, that are well adapted for this purpose, but none more so than long tendrils of Ivy, which long retain their freshness; in fact, if left for any length of time, they will take root in the damp sand. Both the green and variegated kinds, if mingled in the arrangement, have a very pleasing effect.—A. HASSARD.

Anemone blanda.—Our correspondents will oblige us by sending blooms of this *Anemone*, *Iris stylosa*, or of any of the winter-flowering Croci in fresh and good condition.

A SELECTION OF PLANTS AND SHRUBS FOR A COOL ROOM.

WITH A TEMPERATURE OF FROM 35° TO 45° FAHR.

ACCORDING to Dr. Regel, the following rather extensive list of plants and shrubs comprehends the names of kinds which he has proved to do well in cool rooms:

<i>Acacia</i> <i>alata</i> <i>decumbens</i> <i>dentifera</i> <i>dodonaefolia</i> <i>falcata</i> <i>floribunda</i> <i>heterophylla</i> <i>juniperina</i> <i>longifolia</i> <i>Melanoxylon</i> <i>micrantha</i> <i>micronata</i> <i>Oxycedrus</i> <i>verticillata</i>	<i>Acerus</i> <i>gramineus</i> , fol. var. <i>Agapanthus</i> <i>umbellatus</i> <i>Agathaea</i> <i>ameloides</i> <i>Agave</i> <i>americana</i> , and all the other species <i>Anigozanthus</i> <i>coccineus</i> <i>Araucaria</i> <i>excelsa</i> <i>Arbutus</i> <i>Andrachne</i> <i>Unedo</i> <i>Arundinaria</i> <i>falcata</i> <i>Aspidium</i> <i>decompositum</i> , with vars. <i>falcatum</i> <i>proliferum</i> <i>Shepherdii</i> <i>Sieboldi</i> <i>varium</i> <i>Asplenium</i> <i>furecatum</i> <i>marinum</i> <i>Geringianum</i> <i>Aucuba</i> <i>japonica</i> , with vars. <i>himalaica</i> <i>Azalea</i> <i>amena</i> <i>indica</i> , with vars. <i>ledifolia</i> <i>Azara</i> <i>Gilliesii</i> <i>integrifolia</i> <i>Bellis</i> <i>perennis</i> fl. pl. <i>Bambusa</i> <i>nigra</i> <i>reticulata</i> <i>Berberis</i> <i>Aquifolium</i> <i>actinacantha</i> <i>Beallii</i> <i>Darwinii</i> <i>Fortunei</i> <i>japonica</i> <i>repens</i> <i>Benafortia</i> <i>decussata</i> <i>splendens</i> <i>Bouvardia</i> <i>hirtella</i> <i>Jacquinii</i> <i>leiantha</i> <i>splendens</i> <i>versicolor</i> <i>Calceolaria</i> <i>integrifolia</i> <i>hybrida</i> <i>rugosa</i> <i>violacea</i> <i>Camphora</i> <i>officinalis</i> <i>Cassine</i> <i>capensis</i> <i>Ceanothus</i> <i>azureus</i> <i>Citrus</i> <i>Aurantium</i> , with vars. <i>Clematis</i> <i>azurea</i> <i>florida</i> <i>Jackmanni</i>	<i>Clematis</i> <i>patens</i> <i>lanuginosa</i> <i>Clethra</i> <i>arbores</i> <i>Coccoloba</i> <i>ageratoides</i> <i>Cordylone</i> <i>australis</i> <i>Banksii</i> <i>Cotoneaster</i> <i>buxifolia</i> <i>microphylla</i> <i>rotundifolia</i> <i>Capher</i> <i>agnea</i> <i>Cytisus</i> <i>albus</i> <i>chrysobotrys</i> <i>Daphne</i> <i>hybrida</i> <i>indica</i> <i>odora</i> <i>Datura</i> <i>arbores</i> <i>sanguinea</i> <i>cornigera</i> <i>suaveolens</i> <i>Dianella</i> <i>cernict</i> <i>elegans</i> <i>strumosa</i> <i>Dianthus</i> <i>Caryophyllus</i> <i>Diplacus</i> <i>glutinosus</i> <i>puiceus</i> <i>Elaeagnus</i> <i>conferta</i> <i>pungens</i> , with vars. <i>Escallonia</i> <i>macrantha</i> <i>rubra</i> <i>Eucomis</i> <i>punctata</i> <i>Eugenia</i> <i>Ugni</i> <i>Econymus</i> <i>japonicus</i> , with vars. <i>Eupatorium</i> <i>haageanum</i> <i>Weinmanni-</i> <i>anum</i> <i>Fragaria</i> <i>indica</i> <i>Fuchsia</i> <i>coccinea</i> , with vars. <i>corymbiflora</i> <i>fulgens</i> <i>globosa</i> <i>gracilis</i> <i>microphylla</i> <i>Gardenia</i> <i>Maruba</i> <i>Gazania</i> <i>splendens</i> <i>Genista</i> <i>canariensis</i> <i>ramosissima</i> <i>Spuchiana</i> <i>Gnidia</i> <i>juniperifolia</i> <i>Greigia</i> <i>sphacelata</i> <i>Grevillea</i> <i>punica</i> <i>robusta</i> <i>sulphurea</i> <i>Heliotropium</i> <i>grandiflorum</i> , with vars. <i>peruvianum</i> , with vars. <i>Hydrangea</i> <i>Hortensia</i> , with vars. <i>Jambosa</i> <i>australis</i> <i>Jasminum</i> <i>azoricum</i> <i>fruticans</i> <i>grandiflorum</i> <i>odoratissimum</i> <i>revolutum</i> <i>Laurus</i> <i>nobilis</i>	<i>Leptospermum</i> <i>aculare</i> <i>laecatum</i> <i>Cunninghami</i> <i>grandiflorum</i> <i>lanigerum</i> <i>scoparium</i> , with vars. <i>stellatum</i> <i>sericeum</i> <i>Libertia</i> <i>formosa</i> <i>paniculata</i> <i>pulella</i> <i>Ligustrum</i> <i>ovalifolium</i> <i>Louisea</i> <i>confusa</i> <i>fragrantissima</i> <i>brachypoda</i> , fol. var. <i>Magnolia</i> <i>grandiflora</i> <i>Mesembryanthem-</i> <i>um</i> <i>blandum</i> <i>coccineum</i> <i>calitatum</i> <i>spectabile</i> <i>tigrum</i> <i>variabile</i> <i>violaceum</i> <i>Myosotis</i> <i>azorica</i> <i>Myrsine</i> <i>apicana</i> <i>Myrtus</i> <i>bulata</i> <i>communis</i> , with vars. <i>pulella</i> <i>Nerum</i> <i>Oleander</i> , with vars. <i>Olea</i> <i>europaea</i> <i>Oldenlandia</i> <i>Deppiana</i> <i>Ophiopogon</i> <i>Jaburan</i> , fol. var. <i>Oreodaphne</i> <i>foetens</i> <i>regalis</i> <i>Pelargonium</i> <i>apifolium</i> <i>crispum</i> <i>fragrans</i> <i>graveolens</i> <i>hybridum</i> <i>inquians</i> , with vars. <i>lateripes</i> <i>macranthum</i> <i>lobatum</i> <i>pellatum</i> <i>quercifolium</i> <i>sanguineum</i> <i>tricolor</i> <i>triste</i> <i>odoratissimum</i> <i>zonale</i> , with vars. <i>Petunia</i> <i>nyctaginiflora</i> <i>violacea</i> <i>Philica</i> <i>acerosa</i> <i>ericoides</i> <i>paniculata</i> <i>thymifolia</i> <i>Phormium</i> <i>tenax</i> <i>Phytolitia</i> <i>serrulata</i> <i>Pinus</i> <i>excelsa</i> <i>filifolia</i> <i>Hartwegii</i> <i>leiophylla</i> <i>Montezumae</i> <i>palmistris</i> <i>Teocote</i> <i>Pittosporum</i> <i>Tobira</i> <i>undulatum</i> <i>Plumbago</i> <i>capensis</i> <i>coccinea</i>	<i>Polygala</i> <i>myrtifolia</i> <i>Polypodium</i> <i>Lingua</i> <i>Prunus</i> <i>Laurocerasus</i> , with vars. <i>Pteris</i> <i>cretica</i> <i>flabellata</i> <i>japonica</i> <i>longifolia</i> <i>tremula</i> <i>Panica</i> <i>Granatum</i> , with vars. <i>Rhamnus</i> <i>Alaternus</i> <i>Rhaphiolepis</i> <i>phacostemon</i> <i>Rhodes</i> <i>japonica</i> , with vars. <i>Rhus</i> <i>lucida</i> <i>Richardia</i> <i>athiopica</i> <i>albo-maculata</i> <i>Rosmarinus</i> <i>officinalis</i> <i>Ruscus</i> <i>aculeatus</i> <i>androgynus</i> <i>Hypoglossum</i> <i>Hypophyllum</i> <i>Salvia</i> <i>fulgens</i> <i>patens</i> <i>Grahami</i> <i>obtus</i> <i>officinalis</i> , tri- color <i>Senecio</i> <i>Cineraria</i> <i>Petasites</i> <i>populifolius</i> <i>Serissa</i> <i>foetida</i> <i>Siphocampylus</i> <i>bicolor</i> <i>Skimmia</i> <i>japonica</i> <i>Smilax</i> <i>aspera</i> <i>mauritanica</i> <i>Solanum</i> <i>Capsicastrum</i> <i>jasmoides</i> <i>Pseudo-Capsi-</i> <i>cum</i> <i>Sollya</i> <i>heterophylla</i> <i>Stenocarpus</i> <i>Cunninghami</i> <i>salignus</i> <i>Tasmanica</i> <i>aromatica</i> <i>Tecoma</i> <i>jasmoides</i> <i>Tetranthera</i> <i>launifolia</i> <i>Teucrium</i> <i>Marum</i> <i>Thea</i> <i>Bohea</i> <i>speciosa</i>
---	--	---	--	--

WHAT THE PELARGONIUM SOCIETY HAS TO DO.

THE objects of this society cannot be understood, or nobody would fail to see its importance. Few people appear to know what a number of species of Pelargonium have been at different periods introduced from the Cape into this country; and how few of them are now to be found in any collection! I have myself more than fifty species; but these are nothing to those which, looking at London's "Hortus Britannicus," must have been known, at some time, to cultivators in this country. Now, when we reflect that all our beautiful show kinds—French, fancy, zonal, nosegay, and double varieties—have originated from these species, not forgetting such old favourites as Unique, Mangel's Variegated, Sapeflorens, Quercifolium coccineum, Little Pet, &c., surely we may expect to effect crosses, the results of which may be valuable. To this end we offer £3 and £2 for six distinct ornamental species, the intention being to provide, as it were, raw materials for the hybridist. Then we offer prizes of £2 and £1 for the best hybrids, that all may see what each has accomplished. Liberal prizes are also offered, open to all growers, English and foreign, for zonals and nosegays, including a class of thirty distinct plants in small pots, in order that the lovers of this useful family may have an opportunity of seeing the best. What is there in all this to provoke opposition? As to Mr. Irvine's remarks (see p. 578), if the results obtained from crossing two plants of a distinct family or species is the production of a plant which does not happen to please him, is the practice of crossing and hybridising to be discouraged? What would our gardens be if all varieties so produced were to be destroyed? Would he like, either, in the case of fruits or flowers, to return to species only? Is there any more force in the objection to personal names being attached to florists' varieties of any flower? London strongly objected, and I think rightly, to botanical names of Latin and Greek origin being attached to mere varieties of any plant. Perhaps Mr. Irvine would like the Lancashire Gooseberry grower to christen his Rough Red "*Rugosus coccineus*." I should like to see societies for the improvement of every class of plants in cultivation. To bring together men engaged in a common object must tend to mutual improvement. The man of narrow mind, whose great object has been to keep the little he knows secret from all, soon finds he knows but little, and with the hope of knowing more, will soon be anxious to contribute his mite of knowledge to the common stock. Then again, how far discussions, in which cultivators, hybridists, and botanists are concerned, are interesting, can only be known to those who have taken part in them. Some appear to think that the greatest object of those who try their hands at hybridisation and crossing is money making. This is a mistake; like inventors they will go on, because they must go on, whether they make money or not. The man who has raised a new plant from seed feels he has effected something, which the French express by the word "*creation*." If it is the result of what had been before thought a difficult or impossible cross, no doubt a feeling of pride mingles with his pleasure; and perhaps it is quite an after-thought how much he can make of it in the way of money. It was no mean motive, I presume, which induced Major Clarke to take to the crossing of Cotton. The late Mr. Cunningham, of Edinburgh, derived more pleasure from teasing the *savans* with his *Brianthus erectus*—a cross between a *Rhododendron* and an Irish Heath—than ever he did from selling it. Who believes that the late Mr. Donald Beaton thought chiefly of money when he spent his time amongst his favourites? No sensible man despises well-gotten money, but there is a pleasure in the attempt to discover what is possible in the way of raising new fruits and flowers quite apart from money making. Let Mr. Irvine, then, reconsider the matter; though our object may not be his, we may gain knowledge which may be useful to others engaged in improving quite a different class of plants. If he joins us, perhaps he will find more than he expects to interest him. I only know of one class who are likely not only to refuse to join our society, but from whom we expect opposition—those whose only object has hitherto been to get hold of a new plant for as little as possible, and send it out to the public for as much as they can get, at the same time leaving the public to believe that the credit of raising it belonged to them. This class is sure to object to our rule that every plant shall have the raiser's name attached to it. Honour to whom honour is due is our motto, and I know men who will strongly object to this. We do not expect to see their names as members of our society, or to get their guineas for our prize list.

Chilwell.

J. R. PEARSON.

Luxuriant Vine Growth the best Cure for Vine Pest.—M. Signoret has just sent in to the Academy of Sciences an interesting paper on the different species of Phylloxera; he has, moreover, made known a new type of that insect, possessing all the characters

of Phylloxera, but, in some respects, differing from it. If, instead of ascribing the Phylloxera epidemic to a few solitary insects possibly imported from Ohio or California, viticulturists had dropped that part of science which consists in raising artificial boundaries, where Nature has created none, and simply considered Phylloxera in the light of vermin attacking every diseased or weakened plant, they might probably have had recourse to the most rational way of ridding their Vineyards of such pests, *i.e.*, letting them alone—without pruning at all for a few years. Good long wild canes would tend to promote good long roots and healthy rootlets, and thus choke off the pest by excess of sap. Of course, the weakest plants might die, but part of the Vineyard might be saved. It would be incredible if cart-load after cart-load of prunings could be taken away from a Vineyard, year after year; and for hundreds of generations Vines could be propagated from cuttings, without a deleterious effect on the plants being experienced. We see that pruning has had that effect upon some very ancient kinds of Pears, as for instance, Chaumontel and St. Germain, which, if they have not died out completely everywhere, have survived only on account of having been grown now and then, and here and there, as *bona-fide* orchard standards, thus keeping up in certain localities a supply of healthy grafts. The "*degenerescence*" of Pears (an erroneous French term) has long since been proved to the satisfaction of the Société centrale d'Horticulture of France, not to be in the slightest degree attributable to a prolonged reproduction from grafts, as the grafts of healthy plants invariably produce an equally healthy tree, provided the operation has been properly performed.—F. T. P.

THE HOUSEHOLD.

Three Little Dishes of Apples.—1. Roll out a little piece of light pastry tolerably thin; place in it a large Apple of a good baking kind, pared and cored; cover it well with the paste and secure it firmly; bake it in a temperate oven. Four of these turnovers (as they are called) make a dish; they are good either hot or cold. 2. Stew six or eight good baking Apples (pared and cored) until they are tender, let them cool, and mix them with the yolks of two eggs and enough sugar to sweeten them. Spread this mixture on a dish, cover the top with fine bread crumbs and a small quantity of dissolved butter, and bake for a quarter of an hour. 3. Boil 1½ lbs. of loaf sugar in a pint of water for a few minutes, add 2 lbs. of good cooking Apples; let these all boil together until the mixture is tolerably stiff; just before removing it from the fire, add the grated rind of two lemons; press it into moulds which have been previously dipped into cold water (and not wiped), when this *gâteau* (as it is called) is turned out on a dish, ornament it with blanched almonds; pour a custard or some whipped cream round it.

Apples.—A very nice way of using Apples is to slice some into a dish as for a pie, with some sugar and Lemon peel. Make a thick custard of corn flour, milk, and sugar, flavoured with Almonds; pour the custard on the Apples, and bake an hour or till the custard is brown.

Lemon Pie.—For four pies: To twelve eggs, whites and yolks, well beaten together, put four teacupfuls and eight level tablespoonfuls of white coffee sugar; rub eight level tablespoonfuls of sifted flour into one teacupful of cold water; add the grated rinds and the juice of six large Lemons; mix all together, and bake immediately in one crust. For each pie, beat until stiff the whites of two eggs; add two tablespoonfuls of pounded loaf sugar; put on this frosting and bake three minutes.

Lemon Butter for Tarts.—1 lb. of pounded loaf sugar, ½ lb. of butter beaten to a cream, the grated rinds of two Lemons, and the juice; let these simmer in a well-tinned saucepan on the fire for ten minutes, then add five eggs, well beaten, stir the mixture over the fire for a few minutes longer, but do not allow it to boil (a little more sugar may be necessary), it is then ready for use.

PERSONAL.

THE following members constitute the committee of the Pelargonium Society for the first year, viz.:—Mr. H. Webb, chairman; Messrs. W. Browse, H. Cannell, J. Denny, M.D., J. Fraser, P. Grieve, J. George, Dr. Hogg, S. Hibberd, W. B. Kellock, F. R. Kinghorn, T. Laxton, J. Laing, F. Miles, T. Moore, Dr. Masters, J. R. Pearson, R. B. Postans, J. D. Pavle, Rev. C. P. Peach, Jean Sisley, G. Smith; Dr. Denny, treasurer; Mr. T. Moore, hon. sec.—Mr. T. Baines, one of the most successful plant growers of the day, proposes to practice as a landscape gardener, and also to give advice on cultivation and garden-management. Mr. Baines's address is Avenue Road, Southgate.—Mr. George Thomson, hitherto superintendent of the out-door department at the Crystal Palace, will, with the new year, take charge of the entire horticultural department, in doors and out, at the Crystal Palace.
